In the last stages of the disease, lifting and nursing care can become a problem. The use of the exercise program and suitable braces will allow the child to remain at home. Orthopedic braces will also prevent the skeletal deformities and help the child maintain his mobility; but they may be shunned by the parents. Help the parents to emphasize their child's abilities, not his disabilities. As one doctor puts it, "Don't say he can't walk without braces—why not say he *can* walk—with braces?"

A Procedure for Range of Motion

General principles:

- Do not exceed your patient's existing range of motion.
- Do not use force.
- Keep all movements within a pain-free range.
- Do all movements smoothly and slowly.
- Do each movement three times during an exercise period.
- Do the exercises at least twice a day.

Head: (Figures 1, 2, and 3)

1. Bend head forward.
2. Bend head backward, keeping chin in.
3. Bend head toward left shoulder, then straighten. Bend head toward right shoulder, then straighten.
4. Turn face to left side, then face forward. Turn face to right side, then face forward.

Figure 1

Figure 2

Figure 3

MUSCULAR DYSTROPHY

Trunk : (Figure 4)

1. Bend body forward.
2. Bend body backward, keeping stomach muscles tight.
3. Bend body left, then straighten. Bend body right, then straighten.
4. Twist body left, then forward. Twist body right, then forward.

Figure 4

Shoulder : (Figure 5)

1. Raise arm forward and upward.
2. Raise arm sideways and upward.
3. Put palm of hand on back of neck, then bring hand down under arm, touching back of hand to shoulder blades.

Figure 5

Elbow :

Bend arm until finger tips touch shoulder, then straighten arm.

Forearm :

With elbow bent at a right angle, with palm down—turn palm up, next turn palm down.

Wrist :

1. Move hand forward, then move hand backward.
2. Move hand toward thumb, then toward little finger.

Fingers and thumb :

1. Bring tips of fingers to palm of hand, then straighten fingers.
2. Spread fingers wide apart keeping fingers straight, then bring fingers together.

Continued

DIAGNOSTICS

3. Keeping fingers straight, bend hand at knuckles.
4. Bend thumb to center of palm, keeping thumb close to hand, then straighten thumb.
5. Place thumb in front of forefinger, bring thumb straight out, then bring thumb back to forefinger.
6. Touch tip of thumb to tip of little finger, open hand wide; do this with each finger.

Hip: (Figure 6)

1. Bend hip with flexed knee.
2. Move leg backward as far as possible, keeping knee straight, then return it to starting position.
3. Move leg out to side as far as possible, keeping knee straight and toes pointed straight ahead; return it to starting position.
4. Sitting with lower part of leg hanging down, move one foot inward across other leg, rotating thigh outward.
5. Sitting with lower part of leg hanging down, keeping knees together, move one foot away from other foot rotating thigh inward.

Knees: (Figure 6)

Bend knee as far as possible, straighten leg.

Figure 6

Ankle:

1. Bend foot up; bend foot down.
2. Turn foot in; turn foot out.
3. Turn foot in and up with toes bent down.

Toes:

1. Bend toes down.
2. Bend toes up.

DERIVATIVELY SPEAKING

Lung—from Anglo Saxon *lungen* (light in weight)

Scars

God will not look you over for medals, degrees or diplomas, but for scars.

—Elbert Hubbard

Minnesota Medicine at a Glance

Enteropathogenic *Escherichia Coli* in Children—Needham and Wenzl

Page 1311

The occasional finding of enteropathogenic *Escherichia coli* in the stool culture of infants and children with diarrhea should not be considered diagnostic, for the proportion of healthy infants with these organisms is about the same as the proportion of sick infants with these organisms. No special treatment need be recommended for these sporadic cases. Nevertheless, epidemic infections, especially if they affect hospitalized infants, are of grave concern and many necessitate antibiotic treatment and other special precautions.

Bronchial Asthma—Rowe and Rowe

Page 1321

Rowe and Rowe, practicing in the Bay area of California, believe that food is the sole cause of respiratory manifestations of allergy, as discovered in their practice. Their article emphasizes the importance of the history in asthma. By treating the food allergy they have achieved good results in asthma patients, but no improvement in patients who have emphysema. They have found cereals to be particular offenders.

Hemostasis and Thrombosis—Quick

Page 1333

Doctor Armand J. Quick, discoverer of the prothrombin time and an international authority on coagulation, gives his views on clotting. He sees hemostasis as three phases—vascular, platelets, and coagulation. Of these, the vascular phase accounts for most bleeding problems; and of vascular phase defects, Minot-Von Willebrand syndrome is the most common. This syndrome, although usually mild, commonly causes nose bleeds, gastrointestinal hemorrhage, and menorrhagia. To diagnose it, Doctor Quick suggests physicians use the Duke bleeding time and the aspirin tolerance test. The latter test—or bleeding times before and after a given dose of aspirin—helps physicians to diagnose Minot-Von Willebrand syndrome in patients who bleed or who have subclinical disease.

Angiosarcoma of Lungs—Kern et al.

Page 1339

Two months after onset of hemoptysis, a 57-year-old man underwent lobectomy for possible bronchogenic carcinoma. Pathologic studies showed infarction but no signs of neoplasia. One month later, biopsy of the lung revealed atypical cellular proliferation that in some places suggested Kaposi's sarcoma. The patient died two months later. Autopsy disclosed tumor nodules throughout the lungs. The left adrenal was replaced by a large mass. The pulmonary nodules contained neoplastic cells apparently of endothelial origin. The adrenal mass was made up of neoplastic spindle-shaped cells.

This case represents a rare primary angiosarcoma of the adrenal with either metastatic or simultaneous multifocal pulmonary involvement.

Golden Anniversary

Dilantin® (diphenylhydantoin)

PARKE-DAVIS

In untold thousands of epileptic patients... Dilantin has been, and continues to be, the bedrock of therapy.

DILANTIN is useful in the treatment of grand mal epilepsy and certain other convulsive states. Its use will prevent or greatly reduce the incidence and severity of convulsive seizures in a substantial percentage of epileptic patients, without the hypnotic and narcotizing effects of many anti-convulsant drugs.

PRECAUTIONS: Periodic examination of the blood is advisable. Nystagmus in combination with diplopia and ataxia indicates dosage should be reduced. The possibility of toxic effects during pregnancy has not been explored. **ADVERSE**

REACTIONS: Allergic phenomena such as polyarthropathy, fever, skin eruptions, and acute generalized morbilliform eruptions with or without fever. Rarely, dermatitis goes on to exfoliation with hepatitis, and further dosage is contraindicated. Gingival hypertrophy, hirsutism, and excessive motor activity are occasionally encountered. During initial treatment, side effects may include gastric distress, nausea, weight loss, nervousness, sleeplessness, feeling of unsteadiness. Macrocytosis, megaloblastic anemia, leukopenia, granulocytopenia, thrombocytopenia, pancytopenia, agranulocytosis, and aplastic anemia have been reported. Nystagmus, lymphadenopathy, lupus erythematosus, erythema multiforme (Stevens-Johnson syndrome), and a syndrome resembling infectious mononucleosis with jaundice have occurred. DILANTIN is supplied in several forms including Kapseals® containing 0.1 Gm. and 0.03 Gm. diphenylhydantoin sodium.

Parke, Davis & Company, Detroit, Michigan 48232

The color combinations of the banded capsules are Parke-Davis trademarks. The orange-banded white capsule identifies Parke-Davis 0.1 Gm. diphenylhydantoin sodium; the pink-banded white capsule 0.03 Gm. diphenylhydantoin sodium.

BSP® DISPOSABLE UNIT

HW&D BRAND OF SODIUM SULFOBROMOPHTHALEIN INJECTION, USP

(50 mg. per ml.)

BSP®

BROMSULPHALEIN®

IN A COMPLETE,

STERILE,

DISPOSABLE,

& ECONOMICAL

PATIENT-UNIT.

BSP, one of the more valuable single laboratory procedures for determining hepatic function, is now packaged in a complete individual patient-unit.

Each BSP Disposable Unit contains a sterile syringe with the 5 mg./kg. BSP dosage schedule imprinted on the barrel, a sterile needle, alcohol swab and a 7.5 ml. or 10 ml. size ampule of terminally sterilized Bromsulphalein solution.

This all-inclusive disposable put-up lessens the chance of cross-infection and saves time and labor — the most costly commodities.

HYNISON, WESTCOTT & DUNNING, INC.

(BSP03)

BALTIMORE, MARYLAND 21201

Picture of painful myositis

treated with Parafon Forte® TABLETS

Paraflex® (chlorzoxazone)* 250 mg.
Tylenol® (acetaminophen) 300 mg.

Parafon Forte helps to relieve pain, restore mobility . . . stop pain-spasm feedback

Here is why. PARAFON FORTE provides:

a nonsalicylate analgesic equal to aspirin for the relief of pain,^{1,2} yet unlikely to produce the irritation to the gastric mucosa so often associated with salicylate therapy³

and a skeletal muscle relaxant shown to have up to a 6-hour span of action,⁴⁻⁶ and to retain effectiveness even on continued administration,⁵⁻⁷ but which does not have the central effects of tranquilizing compounds.

Prescribe PARAFON FORTE for lasting spasmolysis and analgesia in sprains, strains, myalgias, low back pain, bursitis and other musculoskeletal disorders. Your patients will appreciate the restored comfort and lasting freedom of movement it usually provides.

Cautions and side effects: Use with caution in patients with known drug sensitivity. If a hypersensitivity reaction or symptoms suggestive of liver dysfunction are observed, the drug should be stopped. Occasionally, drowsiness, dizziness, light-headedness, malaise, overstimulation or gastrointestinal disturbances may be noted; rarely gastrointestinal bleeding, allergic skin rashes, petechiae, ecchymoses, angioneurotic edema or anaphylactic reactions may have been drug associated. While *Paraflex* (chlorzoxazone) has been suspected as being the cause of hepatic toxicity in approximately eighteen patients, it was not possible to state that the dysfunction was or was not drug induced. **Dosage:** Two tablets q.i.d. **Supplied:** Scored, light green tablets, imprinted "McNEIL"—bottles of 100.

GENERAL INFORMATION

Authors

Send manuscripts for consideration to MINNESOTA MEDICINE, 375 Jackson Street, St. Paul, Minnesota 55101.

Bibliographic references should conform to the method used by Index Medicus. A maximum of 12 references will be published, but all references will appear in the reprints.

Illustrations, photographs, tables, graphs, and pen and ink drawings are encouraged. If the drawings are not acceptable they will be commercially reproduced and the author will be billed.

All manuscripts will be edited and stylized to conform to the format used in MINNESOTA MEDICINE. The content of the manuscript will not be altered.

Minnesota Medicine Award

An award will be given at the annual meeting to the author of the most meritorious manuscript for the preceding year.

DORSEY "FLU-GRAM"

DON'T BE LULLED BY RELATIVE LACK OF FLU LAST WINTER. THIS WINTER BE PREPARED: WHEN THE COMPLAINTS ARE COUGH AND CONGESTION, YOU CAN RELIEVE THESE SYMPTOMS WITH TUSSAGESIC TABLETS. ONE TIMED-RELEASE TABLET AT MORNING, MIDAFTERNOON AND BEDTIME BRINGS UP TO 24 HOURS' RELIEF FROM TROUBLESOME COUGH AND STUFFED AND RUNNY NOSE. TUSSAGESIC IS THE FAMOUS TRIAMINIC FORMULA, PLUS THREE OTHER PROVED CONSTITUENTS. MAKES PATIENTS MORE COMFORTABLE. FAST. ASK YOUR DORSEY REPRESENTATIVE FOR SUPPLY OF STARTER SAMPLES, OR IF FLU IS ALREADY EPIDEMIC, PHONE COLLECT. SEE BELOW.

each **Tussagesic[®]**

timed-release tablet contains:

Triaminic [®]	50 mg.
(phenylpropanolamine hydrochloride 25 mg., pheniramine maleate 12.5 mg., pyrilamine maleate 12.5 mg.)	
Dextromethorphan hydrobromide	30 mg.
Terpin hydrate	180 mg.
Acetaminophen	325 mg.

Dosage: Adults—1 tablet, swallowed whole to preserve timed-release feature, in morning, midafternoon and at bedtime. **Side effects:** Occasional drowsiness, blurred vision, cardiac palpitations, flushing, dizziness, nervousness or gastrointestinal upsets. **Precautions:** The patient should be advised not to drive a car or operate dangerous machinery if drowsiness occurs. Use with caution in patients with hypertension, heart disease, diabetes or thyrotoxicosis.

President's Letter

READ NO further unless you want to hear a small story about one of my own personal experiences, which I thought I would like to pass on to you for what it may be worth.

If you have never been a smoker, this may bore you!!!

If you have ever smoked and quit, we can compare notes!!!

This really is written for those of you who haven't quit smoking as yet and may be toying with the idea, but need a push.

For those of you who intend to continue polluting the atmosphere and yourselves, my story may amuse you, and you can smile cynically to yourselves and call the whole thing quite stupid.

The incident which gave me the idea to write this little piece was that I happened to tell my story to a Ph.D. clinical psychologist friend of mine, with whom I work at the St. Peter State Hospital. I thought no more about it until I discovered that he had switched to cigars after being a heavy cigarette smoker. He informed me that he had given my tale some thought and had been so impressed by it that it is now his intention to quit smoking altogether. I figured it this way. If my story could affect him so much, a *clinical psychologist*, mind you, and a Ph.D., to boot, then it just *might* give some of you an idea to do the same.

There is nothing worse than a reformed rakehell. One becomes a missionary of sorts,

and tries to make his revelation appealing to all he meets!! So pull up a chair, while I spin my tale of sanctification!

It all started in the winter of 1953: the year that the Kent cigarette was introduced. I had attended a medical meeting in St. Louis, where a battery of automatic smokers had been pulling smoke from a dozen brands through filter papers. Lo and behold—there was almost nothing to be seen on the filter paper which came from the Kent brand! Obviously, they were not advertising Camels! At that time I used a filter in a holder, so I put a Kent on the end of that, and what got back to me was a big fat zero as far as taste was concerned. This gave me the idea: a Kent cigarette would be the one to use when I decided to quit. I bought a carton, smoked them up, and haven't touched cigarettes since!!

I began this whole project by telling myself about all the ways that my lousy habit created discomfort for others. I had to admit it. I stunk! Every smoker does, especially to a nonsmoker. If I went visiting and stayed very long, *I had to have a smoke*. Did they mind? Of course not! What else could they say? No one in the home smoked, so there were no ashtrays about, but they would get something for me. Thanks! That's a lovely old China dish! And smoke clings to curtains and clothing for days!

OOPS! So sorry about that hole in your

|| Porphyria

Strange

and

Baffling

Ailment

HARRY W. SHUMAN, M.D., F.A.C.P.
Rock Island, Illinois

W. D. SNIVELY, JR., M.D., F.A.C.P.
Evansville, Indiana

AMONG THE MOST bizarre and weird of ailments is porphyria, a disorder of blood pigment metabolism in which porphyrins are produced in excess. The disease presents a trio of paradoxes: although porphyria is inherited, acute attacks can be precipitated by chemicals; although physical symptoms such as abdominal pain, vomiting and constipation are preeminent, mental disturbances, ranging from emotional instability to psychosis, almost always accompany them; the very therapy which physicians might quite naturally use to treat the mental disturbances actually accentuates the severity of the disturbances.

The disease has played a fascinating role in history, probably causing the alleged insanity of King George III, and possibly the death by burning at the stake of sufferers from porphyria, adjudged werewolves. Of immediate importance, porphyria is not extremely rare. At least 203 cases have been reported; many more have no doubt gone unreported. Every physician should, therefore, be familiar with this strange ailment.

The Nature of Porphyria

An anomaly in pigment metabolism, porphyria represents a group of disorders of porphyrin metabolism or disturbances of pyrrole* biosynthesis. It is usually inherited. Relatively large amounts of uroporphyrins appear in the urine. Usually excretion of coproporphyrins is increased. In some forms of the disease, excretion of porphyrin precursors (delta-aminolevulinic acid and porphobilinogen) is increased.

Based on clinical and biochemical distinctions, one can divide porphyria into two major groups:

Erythropoietic Porphyria

This rare form of porphyria is inherited in either sex as a mendelian recessive trait. It re-

*See Test Your Word Score Page 1513.

sults from abnormal heme biosynthesis that leads to overproduction of porphyrins of Type 1 isomer. A defect in the enzyme system of the normoblast causes production of increased quantities of Type 1 uroporphyrin. Deposits of uroporphyrin 1 into the skin apparently cause photosensitivity.

Skin lesions, such as a bullous-vesicular dermatitis (hydraea aestivale) occur on exposed surfaces. Hypertrichosis*, melanosis and increased susceptibility of the skin to trauma are seen, as are hemolytic anemia and splenomegaly. Teeth may turn red. Bones may appear red at postmortem. The urine is pink or red and contains large quantities of uroporphyrin 1 and coproporphyrin 1.

Treatment includes avoidance of sun exposure, protective ointments, anti-inflammatory ointments and, in some instances, splenectomy.

Hepatic Porphyria

a. Acute Intermittent Porphyria

This variant of porphyria is believed inherited as a mendelian dominant trait. It is caused by overproduction of the porphyrin precursors, delta-aminolevulinic acid and porphobilinogen, resulting from disturbances of pyrrole biosynthesis. Porphobilinogen and porphyrins accumulate in the liver. Affected persons may have no symptoms or may show clinical manifestations of varying severity. The disease may be without symptoms for long periods, with acute intermittent attacks.

The most common manifestations are paroxysms of abdominal pain, usually colicky and associated with vomiting, distention, and diarrhea or constipation. Colic can mimic a number of acute abdominal conditions. It is usually accompanied by leukocytosis and gastrointestinal spasm. Various neurologic disturbances may occur suddenly—so may convulsive seizures. Most patients develop psychiatric manifestations ranging from irritability to major psychoses. *Photosensitivity does not occur nor do cutaneous lesions.*

Although the urine usually is colorless, it may become wine-colored or black when exposed to sunlight. It contains large quantities of porphobilinogen, usually with increased

amounts of delta-aminolevulinic acid and of uroporphyrins and coproporphyrins. Porphyrins can be studied through their properties of fluorescence with chromatographic methods, melting point of methyl esters, and characteristic spectral absorption bands. Family studies are indicated when an active case is encountered.

Therapeutic measures include chlorpromazine, electrolyte replacement therapy, adrenal steroids, and adenosine monophosphate.

Barbiturates, infections, alcohol and toxic agents such as lead may produce attacks. Use of analgesics and sedatives should be minimized.

b. Photosensitive Hepatic Porphyria (*porphyria cutanea tarda*)

• Hereditary Form

This form of the disease usually develops after age 20. Apparently it is a disturbance of hepatic catalase metabolism associated with accumulation of uroporphyrins in the liver. They are also deposited in the skin, causing photosensitivity. There is continuous excretion of large amounts of coproporphyrin in the feces during latent and active periods. During the active periods, the urine contains large amounts of porphobilinogen and delta-aminolevulinic acid, plus uroporphyrins and coproporphyrins.

• Symptomatic Form

This form may be acquired. Impaired liver function underlies it. However, additional factors may be responsible, such as hepatoma, exposure to certain industrial chemicals, lead intoxication, ingestion of flour grown from seed wheat in contact with hexachlorobenzene, and alcoholic or nutritional cirrhosis. The urine contains a marked increase of uroporphyrins and coproporphyrins, but normal amounts of porphobilinogen and delta-aminolevulinic acid.

Treatment includes protection from the sun's rays; high protein diet; avoidance of alcohol, barbiturates and sulfonamides. Chlorpromazine may be useful.

c. Mixed Porphyria

Combined intermittent and photosensitive hepatic porphyria includes the rare cases in which paroxysms of abdominal pain and neurologic manifestations combine with photosen-

*See Test Your Word Score Page 1513.

sitivity. This form is hereditary. The urine shows a normal or a red color and contains large amounts of uroporphyrins and coproporphyrins.

A Nightmare Disease

Over the centuries, porphyria has made life

Fig. 1—King George III

a living nightmare for its victims and a diagnostic nightmare for physicians. Illis, of Guy's Hospital, London, has called attention to the striking similarity between the several manifestations of porphyria and the descriptions in older literature of werewolves. He believes that the red teeth, the passage of red urine, the nocturnal wanderings, the facial lesions with flaring, wolf-like nostrils, the mutilation of the hands, could well have suggested transformation into a werewolf in primitive, fear-ridden communities.

Much closer to the present is the case of King George III, of England. Although most of us were not presented with a picture complimentary to this monarch in our school days, since he was responsible, in part, at least, for the American Revolution, he was in retrospect one of England's more competent, dedicated rulers, until he had his first attack of what Macalpine and Hunter believe to have been a classic case of porphyria.

Certainly the classic picture of the illness of George III, beginning about the year 1767, appears to meet the criteria for porphyria. The king had his first major attack in 1765, at the age of 26 or 27. He was to have at least five major and four minor attacks before he died January 29, 1820, in his 82nd year, blind, deaf, and generally miserable. Most of his attacks started in winter, and each attack left him increasingly wasted and weak. In addition to manifesting almost all of the clinical findings of porphyria, he was said to have passed "bloody water" during one period of 16 hours, and water of a deep color, leaving a pale blue ring upon the collecting vessel, on another.

All in all, the king's illness was a long and sorrowful one in which he suffered "severely from his affliction, pitifully from his treatments, and miserably from his management . . ." One of his physicians, Dr. Francis Willis, who boasted that he broke in patients as he did horses, ordered the king clapped in a "winding sheet," or a restraint chair (the king bitterly dubbed this his "coronation chair"), or in a strait waistcoat with his legs tied to the bed. Of sound mentality, at least during his early years, he said pathetically in 1801: "I do feel myself very ill, I am much weaker than I was, and I have prayed to God all night that I

might die, or that He would spare my reason . . . should it be otherwise, for God's sake keep me from your father [Dr. Francis Willis]."

Since acute intermittent porphyria is a familial disease, relatives can be expected to develop it. The younger sister of King George III, Caroline Matilda, died at the age of 24 from an illness said to be completely compatible with a fulminating attack of acute intermittent porphyria. Since George III was a member of the House of Hanover, research into the medical histories of the numerous members of his family—many of whom lived abroad—might prove most illuminating.

Case Report

In the case here reported, acute intermittent porphyria was associated with myocardial infarction. An attack was precipitated by the administration of barbiturates before the diagnosis was made. The combination of two major ailments offered a perplexing diagnostic problem. Myocardial infarction associated with acute intermittent porphyria occurs infrequently. The syndrome should be suspected when the characteristic radiating arm pain of myocardial infarction is accompanied by generalized abdominal pain and psychologic abnormalities.

History

A 55-year-old white male, who farmed and operated an automobile crane for a livelihood, first noticed intermittent bilateral arm pain early in January, 1963. On January 30, he awakened in the early morning with intensified arm pain accompanied by what he described as a "strangling feeling in the back of the head." His arms felt "as though they were breaking off." On the morning of the following day he consulted his family physician. A chest x-ray revealed no abnormalities; an electrocardiogram was interpreted as indicating myocardial ischemia. The patient continued working until February 14, 1963, when the senior author saw him.

The past history revealed that the patient had experienced mild intermittent pain in the arms and shoulders for the previous one or two years, not always associated with exertion. Also about two years previously, the patient had passed some dark-colored urine believed at the time to be bloody. There was no pain or urinary tract symptoms at the time, nor was there a repetition of the episode.

The patient's wife, with diabetes, was 55. A son, aged 32, was in good health. The father died at the age of 51 as a result of an accident, the mother at the age of 47 because of "heart trouble with dropsy." The patient had three brothers, aged 72, 68 and 57, in good health.

Physical Examination

The patient was physically well developed; pulse rate 80 and regular, blood pressure 150/80, respirations 24 per minute, oral temperature 99.8F., weight 68 kg. and height 167 cm. He was well oriented and did not appear ill. His voice was high-pitched, and he was apprehensive. The skin of his face was more pigmented than the rest of the body; however, there were no areas of depigmentation elsewhere. Telangiectatic arterioles were prominent over both cheeks and the bridge of the nose. There were several artificial teeth in the upper jaw. The tongue was coated and brownish in color. Otherwise the head and neck were normal.

The anteroposterior diameter of the chest was within normal limits. Expiration was slightly prolonged with scattered rales in each lung base. No cardiac abnormalities were discovered. The liver edge was not felt, nor could the spleen be palpated. The

Fig. 2—Serial tracings of acute posterior myocardial infarction with healing and stabilization.

prostate was of average size, smooth and regular. Rectal examination was negative.

Neurological examination revealed hyperactive deep tendon reflexes in both arms. No abnormalities of the cranial nerves were detected. Tremors of both hands and marked adiadosokinesis* of both wrists were present. The abdominal reflexes were diminished and the cremasteric reflexes hyperactive. Deep tendon reflexes were absent at the knees, although the ankle jerks were increased. There was unsustained bilateral ankle clonus. When the patient stood, he had a vacant, staring expression and either ignored questions or responded slowly to them.

Progress

Since the patient refused to remain in bed and was restless and agitated and complained of aching in the arms as well as severe abdominal distress, he was hospitalized on February 17. Because of his restlessness, barbiturates were started. Severe intermittent arm pain associated with diffuse abdominal cramps and backache continued. The abdominal pain was most distressing to the patient and was accompanied by intractable constipation which failed to respond to laxatives and for which the patient continually requested enemas. On several occasions he sat in a bathtub of warm water to obtain relief. Following this therapy, he lay across the bed on his abdomen.

An x-ray of the lower bowel was done because of the obstinate motor inactivity and reported "... a gaseous distention of the intestine involving some of the small intestine, as well as the large bowel, as far as the region of the splenic flexure. Multiple fluid levels are present. The pattern at this time suggests the presence of a large bowel obstruction."

A follow-up barium study revealed that "the colon is filled from rectum to the caecum and no lesion is found. Evacuation is incomplete. Impression, normal colon; previous distention of March 10th has subsided." An electrocardiogram done on March 18 revealed evidence of Q waves in Lead₂ and Lead₃ with a characteristic posterior wall infarction pattern.

The dose of barbiturates was increased to lessen the patient's discomfort and abnormal mental state; the total amount of sodium pentobarbital administered was 4.7 grams. Although he had not used alcohol before, he managed to obtain a quart of wine which he drank secretly from time to time. At his own insistence, he was returned home.

Laboratory Data

After 24 hours the patient's wife insisted that he be readmitted to the hospital, where his behavior was characterized by increased agitation and his backache was so severe he could not lie down. He was extremely irritable, had a staring fixed expression, and was stuporous with catatonic manifestations. His wife noticed that his urine was dark; examination now revealed porphyrins. The 24-hour urine specimen obtained on March 27 was strongly positive for porphobilinogen, uroporphyrin and coproporphyrin. It was strongly fluorescent through ultraviolet light. The quantitative analysis revealed coproporphyrin 201 μ g/100 cc.; uroporphyrin 189 μ g/100 cc. The porphobilinogen was 3.2 μ g/100 cc.; estimated as 50 mg. per day, assuming a 1500 cc. output.

The delta-aminolevulinic acid was 2.6 mg. per cc.

The hemoglobin was 17.5 gm/100 cc.; red cells 5,750,000, and white blood cells 14,920 with segmented cells 67%; lymphocytes 32%, eosinophils 1%; hematocrit 51%, sedimentation rate (Wintrobe) 5 mm. per hour. The lactic dehydrogenase was 370 units (normal range 100 to 300 units). Total cholesterol was 230 mg. %; Kahn reaction negative; cephalin flocculations for 24 to 48 hours were negative; bilirubin 1 minute was 0 mgm; 30 minutes 0.8 mgm. The urine, normal on first admission, was strongly positive for porphyrins on the second.

On March 29, the cephalin flocculation for 24 hours was negative; for 48 hours it was 1-plus. The transaminase was 62 units; the bilirubin 1 minute 0.1 mgm. %; 30 minutes 0.5 mgm. %. The total protein was 5.4 Gm. %; total cholesterol 196 mgm. %. The alkaline phosphatase was 3.3 B.U. units; the thymol turbidity 1 unit; blood urea nitrogen 15.5 mgm. %. The sedimentation was 23 mm. per hour. The electrocardiogram revealed acute posterior myocardial infarction with healing and stabilization (Figure 2).

Additional liver function studies disclosed a thymol turbidity of 1.5 units; bromsulphthalein excretion 11.7%; transaminase 20 units. The cephalin flocculation was negative for 24-hour and 48-hour specimens. The urine was negative to the Watson-Schwartz test.

With the establishment of the diagnosis of porphyria, barbiturates, ordered on first admission to the hospital and continued since, were discontinued. Slowly the patient's mental symptoms disappeared. He became pleasant and cooperative and was discharged April 17, 1963. Follow-up electrocardiogram on November 25 revealed a stabilized, healed infarct with Q₂ and Q₃ residuals. Later tracings were normal except for the residual findings.

Discussion

The severe arm pain experienced by this patient probably stemmed from the myocardial infarction, aggravated by the neuropathy which accompanies porphyria. The neurologic manifestations of peripheral neuritis associated with porphyria are attributed to focal degeneration of axis cylinders, demyelination and Schwann cell proliferation.

Relatively few electrophoretic data on porphyria are available. Examinations of this patient's serum showed slight variations in the

TABLE I

protein components (Table 1). The albumin and gamma globulins were normal. There were slight variations in the beta and alpha 2 globulins, probably not significant. The prealbumins were elevated. The serum iron level was high normal, while the unsaturated iron binding capacity was almost twice normal (Table 2).

TABLE 2

Electrophoretic iron studies serum
iron level 160 ug%.
Unsaturated iron binding capacity 384 ug%.

The crampy abdominal pain and constipation seen with porphyria have not been satisfactorily explained. Attempts to reproduce the symptoms in experimental animals have not been convincing. As the nomenclature for the ailment implies, the presence of reddish or wine-colored urine may be intermittent.

When diffuse, nondescript severe abdominal pain, psychic abnormalities and neuropathy of unknown origin occur together, either as a primary condition or in association with some other clinical syndrome, a Watson-Schwartz test should be done for the presence of porpho-

bilinogen.

Summary

Porphyria, a bizarre and weird disease with a fascinating history, still occurs. The practicing physician should, therefore, be aware of its protean manifestations. He should consider the possibility of porphyria whenever he sees a patient with abdominal pain, vomiting, constipation, muscular pain, tachycardia and psychologic disturbances—or various combinations of these—particularly when the urine is colored.

Patients diagnosed as having porphyria, and their relatives as well, should beware of barbiturates, sulfonamides, alcohol and various other chemicals. The case here reported combines a classic instance of porphyria with myocardial infarction.

Acknowledgment

The authors wish to express their deep appreciation to Doctor C. J. Watson, Professor of Medicine, University of Minnesota, for his kindness in performing quantitative measurements of the porphyrin components and interpreting the results, and to Doctor H. F. Deutch, Professor of Chemistry, University of Wisconsin, for the electrophoretic analysis.

Paradox of Brucellosis

Decreased
Incidence
but
Increased
Difficulty
in
Clinical
Recognition

GILES F. MacDONALD, M.D.*
PATRICK J. KELLY, M.D.**
WILLIAM J. MARTIN, M.D.†
Rochester, Minnesota

IN RECENT YEARS the incidence of brucellosis has considerably decreased in the United States. Paradoxically, for those with a special interest in the disease, diagnosis has become more difficult.

Contributing to this paradox is the fact that the more classic types of the disease are now recognized with relative ease, and management of such cases is generally satisfactory. Consequently, only atypical cases are likely to come under the scrutiny of physicians with a special interest in brucellosis. Some of these atypical cases involve a previous episode of acute brucellosis in which either the disease was unrecognized or less than optimal therapy was given. Such patients present with localized infection, and diagnosis often is comparatively more difficult. Also, among these patients there have been recognized new syndromes of this old disease, such as localized brucellosis of the spleen associated with recurrent constitutional manifestations.¹

Because of these considerations, it appears pertinent to review some of the currently applicable diagnostic and therapeutic facets of brucellosis. Continued interest in the disease by members of our group is attested by previous publications.¹⁻⁹

Some Nosologic Considerations

Members of our group continue to find it convenient to classify brucellosis as (1) bacteremic, (2) serologic, (3) localized, and (4) mixed.

Patients with bacteremic brucellosis generally are acutely and severely ill. In this type the essence of diagnosis is the culturing of brucellar organisms from the blood; serum agglutination titers usually are high and frequently are rising. Currently, this type of brucellosis is rarely encountered at the Mayo Clinic.

*Resident in Thoracic Diseases, Mayo Graduate School of Medicine (University of Minnesota), Rochester.

**Section of Orthopedic Surgery, Mayo Clinic and Mayo Foundation, Rochester.

†Section of Medicine, Mayo Clinic and Mayo Foundation, Rochester.

Patients with the serologic type have acute or subacute systemic manifestations compatible with the disease, but cultures of the blood are negative for brucellar organisms. The essential characteristic in this type is detection of high, and preferably rising, serum agglutination titers. In the past, some workers have referred to this type as acute nonbacteremic brucellosis. Like the bacteremic type, this type of the disease is rarely encountered in our current practice.

Patients with the localized type sometimes are relatively asymptomatic, but the process may produce recurrent systemic manifestations. In our experience, such recurrent systemic manifestations are most commonly associated with localized splenic brucellosis. In localized pulmonary infections, lack of symptoms is common and detection of the lesion on routine roentgenograms of the chest is usual. Less frequently, other sites of brucellar localization, such as the liver and kidneys, may be asymptomatic, or relatively so. In contradistinction to the serologic or the bacteremic type, the process is chronic and the essential diagnostic finding is growth of *Brucella* on culture of the involved tissue.⁹ Agglutination titers as a rule are low or absent in this type, and results of blood cultures are negative; therefore, one's clinical suspicion must be correspondingly heightened if the diagnosis is to be made. In past years at the Mayo Clinic, the combined incidence of the bacteremic and serologic types was about four times that of the localized type; currently, at least, the converse is true.

The mixed type of brucellosis is very rare and is in an indeterminate area among the preceding types. A patient with bacteremic brucellosis and coexistent culturally proved brucellar spondylitis is an example.⁵

Some Clinical Manifestations

In either the bacteremic or the serologic type, such findings as fever, chills, and sweats of acute onset in a patient who has had possible contact with brucellar organisms usually imply consideration of the presence of the disease. In this regard, more than half of the patients studied by members of our group have been farmers or persons otherwise occupied with animal husbandry. Only about 10 per

cent of our patients with brucellosis have been females. In the bacteremic and serologic types of infection, splenomegaly is the most frequent abnormality and occurs in about 25 per cent of patients. In our experience, adenopathy and hepatomegaly each occurs in about 10 per cent of these types.

In contradistinction to the bacteremic and serologic types wherein about 90 per cent of the patients have fever, fever has been noted in less than half of our patients with localized brucellosis. There are some indications that the spleen may be the most common extraskeletal site of localized brucellosis in man. From 1952 through 1964, 10 patients with localized splenic brucellosis have been seen at the Mayo Clinic.⁸ Of the sites of brucellar localization, the following five (in order of decreasing frequency) have been most common in our experience: skeleton, spleen, genitourinary tract, soft tissues, and lungs.

The Spleen and Other Loci

In addition to the spleen, sites of chronic localized brucellar infection associated with recurrent constitutional manifestations are the liver, gallbladder, skeleton, lymph nodes, and ovarian cysts. The symptomatic episodes usually occur several times a year, and 10 years or more may pass before the process is identified. Lasting two to seven days, the episodes may be characterized by chills, fever, sweats, malaise, myalgia, and headache. Other symptoms related to the site of localization may be noted.

When present in localized brucellosis, physical findings are usually indicative of the site of involvement. For example, an enlarged spleen may be palpated in localized brucellosis of the spleen, or swelling and tenderness of a knee may manifest brucellar prepatellar bursitis. Before operation, the surgeon may be unaware of the nature of other localized lesions, notably those of the lungs, and his securing of material for culture may be of extreme value.

The Skeleton

Brucellar spondylitis in which the causative organisms invade an intervertebral disk from a nidus in the vertebral body is the most fre-

quent type of skeletal involvement.⁵ Whenever the so-called disk syndrome is seen in a patient who works with animals, the possibility of brucellar spondylitis should be considered. Back and leg pain, muscle spasm, percussion tenderness, and sometimes even a positive result to the Lasègue test may be noted. In our experience, brucellar spondylitis accounts for almost 50 per cent of the cases of skeletal brucellosis. However, brucellosis rarely involves the cervical spinal column. Osteomyelitis, which constitutes about 15 per cent of the cases of skeletal brucellosis, may involve such regions as the humerus, femur, skull, and ribs and may be manifested by local pain, heat, tenderness, swelling, erythema, and sometimes a variable degree of constitutional reaction. Although brucellar prepatellar bursitis is the lesion in roughly 25 per cent of the cases, brucellar synovitis occurs in only about 10 per cent. Since our report⁵ in 1960 on 36 patients with skeletal brucellosis, we have seen an additional four patients with culturally proved brucellosis of this variety. These patients had lumbar spondylitis, osteomyelitis of the pelvis, and infection of the synovial tissue of the knee and shoulder joint.

Urinary Tract or Liver

Brucellar involvement of the urinary tract may occur without physical manifestations and frequently cannot be differentiated from chronic infections of the urinary tract due to other pathogens, without definitive microbiologic findings.

Localized hepatic lesions caused by brucellar organisms may be asymptomatic or may result in hepatomegaly, jaundice, and constitutional reaction. Jaundice and altered hepatic function also are not uncommon in acute brucellar infection.

Lymphatic and Vascular Lesions

Chronic brucellar infection of a superficial lymph node may result in a draining sinus.

Although rarely causing vascular lesions, brucellar organisms have been cultured from a popliteal aneurysm removed at operation, and cases of brucellar endocarditis have been described.

*See Test Your Word Score Page 1513.

Laboratory Findings

Cultural

Brucellosis is diagnosed with certainty only by cultivation of brucellar organisms from specimens of the patient's blood, body fluids, excreta, or tissues. In bacteremic brucellosis, *Brucella abortus* is grown most frequently on cultures of the blood. In our experience, most localized lesions are caused by *B. suis*.

Serologic

As a generalization, in cases wherein brucellar organisms have not been cultured, the diagnosis of brucellosis should not be made unless brucellar agglutinins are present in high or increasing titer and the patient is strongly suspected clinically of having the infection. The agglutination test can lead to confusion in the form of the so-called anamnestic* phenomenon; in such an instance, the residual agglutination titer from previous brucellosis may be increased by the patient's current and unrelated disease. A previous injection of Brucellergin, a vaccination against cholera, or the presence of tularemia may also induce antibrucellar agglutinins. Our experience in regard to the agglutination test can perhaps be summarized as follows: In bacteremic brucellosis, titers invariably exceed 1:200 at some time during the illness, but in localized brucellosis, titers in more than half the cases do not exceed 1:200 and occasionally are negative. Brucellar spondylitis differs from other types of localized brucellosis in that the agglutination titer is almost always 1:800 or higher.

Hematologic

In most patients with brucellosis, routine hematologic data are of little diagnostic aid. The overall incidence of anemia in these patients is less than 10 per cent, but is more common in patients with the localized type than in those with the bacteremic or the serologic type. In patients with the bacteremic or the serologic type, leukopenia is present in about one third, but leukocytosis is rare. Leukopenia or leukocytosis is present in less than 10 per cent of patients with the localized type; rarely, leukopenia and thrombocytopenia occur as hypersplenic effects in localized splenic brucellosis.¹ The sedimentation rate is elevated in less than

25 per cent of patients and is more likely to be elevated in the bacteremic or the serologic type than in the localized type.

Histologic

In localized brucellosis, the finding of granulomas in infected tissue may be suggestive of the possibility of brucellosis—among other possibilities—but there are no histopathologic criteria by which brucellosis can be diagnosed with certainty. In cases of suspected brucellosis, tissue should be cultured because fluid—from a joint or purulent material from a draining sinus, for example—is sometimes negative for *Brucella* even though the organisms are present in the tissue.

Skin testing of individuals suspected of having brucellosis is not advised, because the correlation between the results of the test and the presence of the disease is low and because confusion may result from the ability of the test to induce antibrucellar agglutinins.

Roentgenographic Findings

In brucellar spondylitis, roentgenograms may reveal involvement of the intervertebral disks and contiguous vertebra, narrowing of the intervertebral space and eventual bony fusion of the adjacent vertebrae, narrowing with parrot-beak exostoses in the healing stage, or, rarely, paravertebral abscesses. In brucellar osteomyelitis the roentgenographic picture is that of medullary destruction, often with periosteal thickening. In brucellar bursitis and synovitis there is roentgenographic evidence of effusion and possible osteoporosis of adjoining bones.⁵ In brucellosis localized to the spleen, roentgenographic evidence of splenic calcification is almost the rule, and barium contrast studies⁶ may reveal the displacement of the gastrointestinal tract by the enlarged spleen. Brucellosis of the urinary tract may result in such urographic findings as calyceal destruction and pelvic dilatation, and areas of calcification may be discernible in the renal mass. As mentioned, pulmonary lesions may be detected on routine roentgenograms of the thorax, which on surgical extirpation and microbiologic study prove to be brucellar granulomas.

*See Test Your Word Score Page 1513.

Therapeutic Considerations

Antibacterial Drugs

Members of our group have continued to prefer use of a tetracycline in combination with administration of streptomycin in the management of most cases of brucellosis. With previous or current intolerance of streptomycin, less than normal renal function, or decreased auditory acuity, we give the tetracycline alone; but this has not been a common occurrence.

Up to the present, in the treatment of bacteremic and serologic brucellosis, we have used 500 mg. of a tetracycline given orally every six hours and 1 Gm. of streptomycin injected intramuscularly twice daily for two weeks. In chronic localized brucellosis, we have reduced the amount of streptomycin to 1 Gm. daily and have continued combined treatment for four weeks.

With the increasing number of potentially ototoxic drugs* and the possibility of auditory damage following their sequential use, we have considered the feasibility of reducing the amount of streptomycin employed in our antibrucellar regimens. In other words, a given patient may require administration of kanamycin for an infection of the urinary tract due to indole-positive *Proteus* organisms and also require vancomycin because of a serious infection due to *Staphylococcus aureus* (especially if he was allergic to the penicillins); then at a later date, he may have brucellar spondylitis. In such a patient there is some doubt whether the daily dose of 1 Gm. of streptomycin for four weeks should be administered. The converse is also applicable, where there is the need to prescribe kanamycin in a patient previously treated with full doses of streptomycin for such infections as brucellosis, tularemia, or enterococcal endocarditis. Consequently, we are considering reducing the daily dose of streptomycin to 1 Gm. in acute infection and to 0.5 Gm. in localized infection, and prolonging therapy an additional one or two weeks. The suggestion of Spink¹⁰ has considerable merit, wherein use of streptomycin should be discontinued after about 10 to 14 days, but therapy with the tetracycline alone should be continued for several weeks. The routine use of a tetracycline alone as an antibrucellar regimen is ob-

jected to because the duration of therapy must be prolonged considerably, the relapse rate in patients so managed may be significantly higher, and the fear that localized brucellosis at a later date may more likely occur in such patients. In patients receiving streptomycin, vestibular and auditory complications are best detected when audiometric and vestibular-turning tests are carried out before therapy, periodically during treatment, and again six months after treatment has been discontinued.

Surgical

The diagnosis of localized brucellosis most often depends on the procurement of material for culture, for example, from a site of osteomyelitis, from a removed spleen in which brucellar organisms have localized, or from an excised infected lymph node.

As a generalization, energetic surgical treatment for brucellosis of the skeletal system is required. An exception to this is brucellar spondylitis, in which the diagnosis almost always can be made by virtue of relatively high agglutination titers and in which the patient usually responds to rest, use of braces or casts, and antibiotic therapy. Of course, a coexisting paravertebral abscess would require surgical drainage. Infected joints and bursae respond well to excision of the synovial tissue and antibiotic therapy. Brucellar osteomyelitis is the hardest of all skeletal brucellar lesions to treat successfully and requires wide drainage and saucerization; unfortunately, secondary pyogenic infection often prolongs morbidity and makes management more difficult.⁵

Comment and Conclusions

Elimination of brucellosis in animals must precede ultimate eradication of the disease in man. Contact with infected animal tissues, ingestion of unpasteurized dairy products, and exposure to brucellar organisms in the laboratory have been the usual modes of human infection.

Contact with infected animals, and especially their products of conception, has been responsible for most human infections rather than ingestion of contaminated milk products. This accounts for the greater prevalence of the disease among such people as dairymen, meat-

packing employees, and veterinarians.

In the last few years, human brucellar infections have been found above the Arctic circle in Alaska.¹¹ Epidemiologic studies appear to indicate that the source of human infection is the caribou and the mode of infection may be ingestion of the infected animal's meat. In communities where caribou meat is consumed, five to 25 per cent of the residents have positive agglutination titers.

Since our initial encounter with the syndrome in 1956, members of our group have described 10 cases of localized brucellosis of the spleen.⁸ Our experiences to date indicate that the syndrome exists as a clinical entity apart from detectable brucellar involvement of other reticuloendothelial organs. This conclusion is based on the fact that the infection apparently has been restricted to the spleen in some cases and on the finding that antibiotic therapy may eradicate the infection in other reticuloendothelial organs but not in the spleen. That is to say, brucellar infection in such tissues as the liver and lymph nodes is eradicable in many cases by antibiotic therapy, but the infection may persist in the spleen despite such treatment and may be curable only by splenectomy. Also, splenectomy provides cultural proof of the suspected disease, removes any hypersplenic effect on the marrow, and allows detection of additional brucellar lesions (such as retroperitoneal abscess) that have occurred in such cases. In localized splenic brucellosis, cultural proof of the infection is especially desirable, since in half of our cases the *Brucella* agglutination titer has been negative or lower than that ordinarily considered as diagnostic.

In regard to patients suspected of having localized brucellosis, but in whom agglutination titers are not diagnostic, demonstration in their serums of blocking antibodies may be helpful.¹² Presence of such blocking antibodies corroborates suspicion of brucellar infection and may eliminate unnecessary operation in chronic infections without splenic involvement. Demonstration of increased amounts of the so-called antibodies in serum sedimenting as 7S globulins may be similarly corroborative of active brucellosis in such cases.¹³

In the rare individual who is unable to accept a tetracycline, one may consider use of drugs such as erythromycin, novobiocin, ampi-

cillin, and chloramphenicol. Erythromycin and novobiocin have given evidence of being efficacious.^{6,14} Chloramphenicol probably has an antibrucellar effect approaching that of the tetracyclines, but its routine use is not recommended because of possible hematotoxic effects. Use of ampicillin has not been sufficiently evaluated as yet.

In most patients with localized brucellar lesions, it is virtually impossible to precisely evaluate the results of antibiotic therapy be-

cause surgical procedures are carried out concurrently. A persistent question is whether antibiotic therapy should be given after surgical removal of what is apparently an isolated locus of brucellar infection. Although individualization of therapeutic effort is a function of the case at hand, we have often recommended antibiotic therapy in such instances. We have made such recommendations because we hoped to eradicate any residual infection in the locus and to subdue any other undetected, currently asymptomatic, area of brucellar residence.

Life Span

People who wish they were as "strong as a horse" or as "contented as a cow" may be surprised to learn which mammal actually lives the longest. It is not the horse, not the cow, not the hippopotamus, not even the durable elephant. The longest-living mammal today is woman. The average girl can expect to live fully seventy-one years. The mighty elephant, once ranked as the longest-living mammal, now lags far behind with its sixty-year life span. The hippo has an expectancy of forty; the horse twenty to twenty-five; and the cow averages from nine to fifteen years. Even men live longer than elephants these days, an average of sixty-five years.

The turtle, which is not a mammal, lives at least a century longer than human beings. But the turtle can't brag about its advanced age and women probably won't, so we men are safe.

Consciousness reigns but doesn't govern.—Valery

|| Varicose Veins

A
New
Surgical
Concept
in the
Treatment

HORACE G. SCOTT, M.D., F.A.C.S.
Minneapolis, Minnesota

VARICOSE VEINS have been attributed to numerous causes. Many factors undoubtedly do play a role in their etiology. I feel, however, that one factor has been entirely overlooked, namely, a partial obstruction of the deep circulation in a relatively high percentage of cases. The obstruction occurs within the femoral sheath located just below the fossa ovale. In the light of these findings, I feel that varicose veins represent the development of collateral circulation as a bypass for the returning venous blood from the lower extremity to the external iliac veins.

About five years ago, several patients were observed with unilateral varicosities. In exploring the sapheno-femoral junction of these patients it was noted that the femoral lymph nodes were often enlarged. Where this was the case, the femoral sheath was found to be extremely tight, constricting the femoral artery and vein at or just below the level of the fossa ovale. It seemed only natural that one should open the femoral sheath and free up the femoral vein to facilitate the return of venous blood through the deep circulation. Following the incision of the sheath the internal and external saphenous veins were then stripped out. Much to my surprise, I found very little evidence of recurrent varicose veins postoperatively. In the past it was not uncommon to note the redevelopment of varicosities within a year or two following the stripping procedure. Since operating on more than one hundred cases in the past five years, I have been impressed with the lessened recurrence of varicosities where the fascia of the femoral sheath has been incised. A second constricting factor has been the presence of a small artery and vein running across the femoral fascia just below the edge of the fossa ovale. In a number of instances these vessels have been the chief constricting factor. In treating this problem we have cut and ligated the vessels in every instance and, in addition, have incised the fascia

longitudinally between the artery and vein. In doing so we have frequently noted that the femoral vein was constricted to about one third or even one fourth its normal caliber. Immediately after incising the fascia, the femoral vein has assumed its normal caliber. Recently venous pressure readings have been taken in the saphenous and femoral veins. The readings in the femoral vein have been taken below the sight of constriction and have revealed that the pressure within the vein is about 25 per cent higher than that in the saphenous vein.

History

From a historical standpoint the treatment of varicose veins has undergone an evolutionary process from simple ligation of the saphenous vein to extensive stripping and multiple ligations. In 1916 Homans first advocated sectioning of the saphenous vein. In 1927 Moschowitz suggested the combined ligation of the long saphenous vein with retrograde injections of the vein. Between 1927 and 1955 further progress in the combined surgical-medical treatment of veins was made. At the present time the accepted method is the stripping out of the entire internal and external saphenous system. In my hands the femoral fascia is also incised longitudinally to free up the deep circulation which has been found to be partially obstructed in about 40 per cent of our cases.

Surgical Technic

Skin Incision

A short incision is made in the upper thigh over the saphenous vein parallel to the groin and about two centimeters below the groin crease. All tributaries to the saphenous vein are first tied off and then the vein is cut distal to its insertion into the femoral vein. Next the femoral fascia is carefully inspected at the level of the fossa ovale. If a constricting blood vessel is present below the insertion of the saphenous vein into the femoral, this vessel is cut and tied.

Incision in Femoral Sheath

A vertical incision is made in the anterior femoral sheath between the femoral artery and vein for a distance of from two to four centi-

Fig. 1.—Technique of femoral fasciotomy in conjunction with internal saphenous vein stripping.

meters or until it fuses with the adventitia of the femoral artery and vein. See illustration. If one's finger can be passed easily beneath the femoral fascia at the fossa ovale no attempt is made to incise the femoral sheath. If this space will not admit the index finger, we have found that the femoral vein is definitely constricted.

Stripping the Vein

After completing the femoral fasciotomy a short incision is then made above the medial malleolus and an intraluminal flexible stripper is passed up through the entire length of the saphenous vein from the ankle to the groin. Then the vein is stripped out. Where perforations are encountered, additional incisions are made and the veins are tied off at the level of the fascia.

Conclusions

The femoral sheath is constricted in a relatively high percentage of patients having varicose veins. This constriction results in a partial obstruction of the venous return through the femoral vein. Incision of the femoral sheath from the fossa ovale down to its fusion with the adventitia of the femoral artery and vein is recommended. Where there are a small artery and vein crossing the fascia below the insertion of the vein, this vessel should also be incised and ligated. If this procedure is carried out in conjunction with a careful stripping out of the internal and external saphenous vein systems, very little recurrence of varicosities will be found during a five-year follow-up period.

Farm Accidents and Their Prevention

An Epidemiological Approach

KENNETH A. MUCKALA, M.D.*
Sioux Falls, South Dakota

RECENTLY I WAS part of a team of physicians who treated a farmer from Nicollet County hospitalized because of a power take-off accident while harvesting soybeans. He had removed the safety shield from the power take-off shaft on his combine while repairing it and, while harvesting beans, had hurriedly jumped off his tractor and caught his heavy, loose clothing in the shaft. The result: multiple fractures of the left arm and amputation of portions of the left hand. He was unable to finish his harvesting, feed his cattle, or do his fall plowing. A man had to be hired to finish the harvesting, some of the cattle were sold at a loss, and this farmer's family suffered economic hardships, when at best, the economic situation of the family farm was tenuous. This story is repeated with variation time and time again throughout our state. This is a complex problem which has not only preventive medicine aspects, but complicated sociological implications as well. Modern agriculture presents unique problems to those engaged in medicine, especially preventive medicine. The farm population is diffuse. The home and the work place are the same. The work force is the whole family, male and female; the young son and the senior citizen. The activities are seasonal; the work techniques and jobs vary by individual; and the weather and climate play an important role. Because accidents are so common in the life of our rural patients and trauma results in a consumption of medical services, it behooves the physician, especially the rural family physician, to play a positive role in preventing these "preventable diseases."

Accidents play a leading role as the principal cause of death in all occupations. From ages one through 34, the leading cause of death is accidents. Agriculture is annually responsible for more occupational deaths than any other major industry in the United States. Three thousand lives were lost while men and women

*Sioux Valley Hospital, Sioux Falls. Formerly with the Department of Public Health and Preventive Medicine, University of Minnesota Medical School.

were working on farms in this country in 1965.¹ Fatal accidents comprise only a small proportion of the total accidents; for every death there are nearly one hundred serious, disabling, crippling injuries which require hospitalization.²

Although industrial death rates have declined significantly in the past several decades, agriculture, because of its individualistic nature, has not enjoyed such good fortune. The occupational death rate among farmers and farm workers has actually increased as noted below:

Accidental Deaths of Farm Residents by Year			
Year	Total	Farm Pop.	Death Rate
1950	15,500	25,058	61.9
1951	15,000	24,160	62.1
1952	14,500	24,283	59.7
1953	13,500	22,679	59.5
1954	12,500	22,099	56.6
1955	12,800	22,438	57.0
1956	12,800	22,362	57.2
1957	12,000	21,606	55.5
1958	11,600	21,388	54.2
1959	11,700	21,172	55.3
1960	11,300	20,541	55.0
1961	8,800	14,803	59.5
1962	8,800	14,313	61.4
1963	8,400	13,367	62.8
1964	8,300	12,954	64.1

Types of Accidents

Tractors

Machinery* is involved in two out of five deaths.⁷ It accounted for 51 per cent of the farm accidents in Minnesota in 1964.⁸ The tractor was involved in 90 per cent of the machinery accidents in Wisconsin in 1961.⁹ Tractor accidents claim the lives of an estimated 1,000 persons annually in the United States.¹⁰ Farmers drive tractors over rough ground at high speeds. Row crop tractors are driven over unsuitable terrain such as steep hillsides and loads are sometimes pulled from rear axle levels and above, thus predisposing to up-ending of the machine. *It is common practice to allow 10-year-old boys to drive tractors over highways and operate machinery with which they are not familiar. They often take their younger brothers and sisters for rides across fields and pastures and occasionally on the highways.* Farmers themselves may be

unaware of the potentially lethal nature of the tractor, and some are run over by their machines because of failing to disengage the engine before dismounting. Others are thrown from their machines while standing on the tractor. Tractors are operated upon the highways at night without proper lighting and reflectors. Below is noted the incidence of different types of tractor accidents in a National Safety Council study of 789 tractor fatalities.

Accident Type and Use of Tractor, 1964

Accident Type	%
Tractor upset	58
Fall from tractor	13
Crushed	9
Run over	8
Motor-vehicle collision	6
Power take-off	3
Other	3
Total	100

Use of tractor	%
Tillage, planting, harvesting	29
Tractor enroute to site	15
Material handling	15
Towing vehicle or implement	11
Passenger transportation	6
Clearing land	4
Stationary power source	4
Other	16
Total	100

Harvesters

Harvesting machinery accounts for most of the farm accidents involving machinery other than tractors. Every fall farmers fall prey to the snapping rolls of the cornpicker. The pickups of combines and haybalers also manage to maim the extremities of countless other farm workers. *Most of these injuries are due to leaving the machinery running while cleaning and servicing.* Often safety shields over drive belts, power shafts, and chains are missing because repairs have been made haphazardly during the periods of peak machine use. Both the age of the machine and the familiarity with its operation are important. In the Dane County study in Wisconsin in 1958, it was found that nearly one fourth of the accidents involving machinery could have been avoided by replacement of worn, loose equipment and the proper use of the machinery.¹²

*Tractor, mower, haybaler, cornpicker, combine, power saw, ensilage cutter, and manure spreader.

Falls

According to most sources falls appear to be the second largest cause of farm accidents and accounted for one fifth of the farm accident fatalities in Minnesota in 1964¹³ and for 27% of the non-fatal injuries in the Dane County study in Wisconsin.¹⁴ Nearly one half of these falls occurred from hay wagons and tractors. Falls from trees, ladders, machinery, and on slippery terrain also account for a large number of accidents. As can be expected, many of these falls occur in and around the home, barnyard, and service buildings. *Unstable, old, wornout ladders, weak hay wagon floors, lack of handholds on machinery, and wet floors greatly increase the chance for a disabling fall.*

Burns

Burns from fire and explosion of combustible material are the third leading cause of farm fatalities due to accidents according to the United States Public Health Service.¹⁵ This has also been true in Minnesota over the last decade.^{16,17} Most of the burns are due to fires and explosions caused by defective or misused electrical equipment, defective heating units, sparks from tractors and rubbish on manifolds, and careless handling of greases and petroleum fuel. *Common offenses include: tractors refueled without shutting off the engine, trash and rubbish accumulating around the farm shop, granary, or barn; and inadequate or defective lighting used around service buildings.*

Animals

Another common accident agent is the farm animal,^{18,19,20,21} involved in an average of 15 per cent of all farm accidents. These accidents frequently involve handling bulls, saddle horses, loose cattle, and small children in animal enclosures such as hog pens.

Tools

Other agents less commonly associated with farm accidents include blows from falling objects, hand tools, poisoning with farm chemicals, and ingestion or inhalation of food or other objects causing obstruction or suffocation. The scope of agents directly related to

the home, drownings, or the family automobile is too wide for this presentation.

Environment

Seasonal

As in any epidemiological study, the environment is an important factor. Environmental factors important in the genesis of farm accidents include: weather, climate, season, temperature, terrain, time of day, length of working hours, lighting, and work area. The incidence of all rural accidents rises rapidly during the summer months and then falls abruptly with the completion of harvest. July and August annually show the greatest percentage of farm accidents.²² This is corroborated by studies done in Minnesota. Thompson noted that rural accidents reached a spring peak in May and a top peak in July, declined in mid-summer, and reached a third peak in October. These peaks seem to correspond to the three common periods of farm work: spring fieldwork, haying and harvesting, and corn picking.²³ Weather appears to have little effect on the rate of accidents; however, one would certainly expect an increase during periods of fog, impending storms, and extreme heat.

Farm Yard

According to the Dane County study done in 1960, nearly 55% of all reported accidents occurred in the barn or around the farmyard²⁴ involving animals, fires and explosions, falls, and blows by falling objects. Poor lighting, dilapidated buildings, slippery footing, and inadequate electrical wiring play a role in these areas. Rough and steep terrain play a part in tractor accidents in fields and pastures. The Dane County study also reports that time of day would also seem to show a relationship to the incidence of farm accidents. There is a definite mid-to-late morning and mid-to-late afternoon increase of accidents with peak hours of 11 a.m. and 5 p.m. Longer working hours during the peak harvest seasons predispose to fatigue, as do lack of rest periods during the day. The individual farmer, who is his own manager and owner, is all too prone to push his work force, namely himself and his family, beyond normal limits.

The Farmer Himself

Perhaps the most important aspect of the epidemiological study involves the host, namely the farmer, his hired help, and his family. Important factors include age, sex, experience, safety education, physical status, fatigue, drugs and medications, accident proneness, and that difficult to evaluate factor, carelessness.

His Children

Thirty to 40 per cent of all farm accidents occur to children and teenagers. According to the National Safety Council one fourth of all tractor victims are under 20 years of age.²⁵ Children are also involved in a major portion of death by drowning and firearms, and in accidents with farm animals. Accidents involving farm machinery are perhaps even more tragic when they involve the life or extremity of a child. It would seem that natural curiosity and lack of respect for dangerous machinery coupled with parental irresponsibility and poor judgement are responsible for these accidents. A child has no reason to be around an operating piece of farm equipment or large farm animals. The best control of this problem, according to Lucas and Wirka at Wisconsin, would be for the farmer to divorce his children from his work around machines as the factory worker does.²⁶ In studies done in Minnesota, the bulk of accidents occurred to persons between 15 and 30 years of age; and the male members of the family stood the greater chance of becoming injured, especially the husband and the son.²⁷

The Hired Help

This lack of trained, experienced labor increases dangers in operating machinery alone and caring for unruly animals. It also means that unskilled, inexperienced members of the farm family are needed to operate machinery and perform dangerous tasks during peak work periods. Often there is a lack of supervision for this unskilled labor, and there is no one to supervise safety practices with even the experienced farm worker.

Fatigue

Fatigue is a major factor in farm accidents.

The farm worker works on his own time and often without interruption. The physical status of many farm workers is unknown. There may be problems involving sight, hearing loss, disabilities, or systemic disease which may enhance the fatigue factor. At times the farmer is unaware of the effects of medications he may be taking which can cause drowsiness, incoordination, and slowed reaction time. Accident proneness, a relatively new concept in the field of accident prevention, plays an indeterminate role in the genesis of agricultural accidents. Industrial studies show that the chronically depressed, neurasthenic, and low-normal intelligence groups have increased numbers of accidents. This probably can be applied accurately to agriculture.

Carelessness

Intimately involved with fatigue and accident proneness is the factor of carelessness and haste. Forty-five per cent of those interviewed in the Dane County study were in a hurry at the time of the accident.²⁸ *Carelessness is probably the largest and most significant factor underlying farm accidents.* Careless repair, simple neglect of equipment, poor judgement in its use, high speeds, and lack of preparation for emergencies all predispose to major proportion of our accidents.

Prevention

Education

The first definite programs of farm safety education were instituted in Minnesota in the early 1930s through the Agricultural Extension Service and the 4-H Clubs. Many rural organizations such as the Farm Bureau and Farmer's Union carry on safety campaigns with educational speeches, demonstrations, and spot announcements in the mass media. Local county extension services and rural Parent-Teacher Associations feature "Farm Safety Night." This year the National Safety Council and U. S. Department of Agriculture sponsored the twenty-third "National Farm Safety Week" focussing national attention on agricultural safety. This "Farm Safety Week" is also complemented by state "Farm Safety Weeks." Perhaps the most effective programs of farm

safety occur in the farm safety projects of 4-H Clubs, high school vocational agriculture classes in farm safety, and adult vocational agricultural classes. These farm safety projects provide extremely worthwhile practice and make participants aware of the many ramifications of accident prevention.

Engineering

In the area of machinery design, it must be conceded that manufacturers build machinery that the farmer will buy on the basis of performance and cost. In recent years more time has been spent by manufacturers in educating the farmer to use his equipment safely by demonstration and increased information in the operator's manual. State agricultural extension services have also made great efforts in promoting design of safer machinery and farm buildings.

Enforcement

Enforcement, which has given great rewards in industrial safety programs, breaks down in agriculture because usually the activities are carried out by the owner-operator on his own premises. Scattered attempts have been made at routine inspection of farm premises by Future Farmer groups and 4-H clubs to detect potential hazards; but in general, these methods of health promotion leave much to be desired. Farm leaders, however, continue to stress education as the most important line of attack.

What more is to be done? A beginning has been made. The first institute of agricultural medicine was established in Poland 15 years ago. The Institute of Agricultural Medicine at the State University of Iowa College of Medicine was established in 1955 to examine the problems of agricultural health, among them farm accidents. Since then, this Institute has made meaningful studies of rural health problems, invented countless safety devices, and most of all, evolved a multidisciplinary approach to agricultural preventive medicine. They have brought together under one aegis physicians, veterinarians, toxicologists, safety engineers, sanitary engineers, and people skilled in anthropology-sociology to study all the elements involved in the detection, evaluation, and control of agricultural health and safety prob-

lems. This "intramural" group is then supported by the community professional group, the "extramural" group, who can actually apply preventive measures.³⁰

Teaching in Schools

Coupled with research and study, there must be an increase in long-range safety and health education to create health and safety consciousness in individuals during a period in their lives when these habits can most readily be taught and accepted—in childhood. Health and safety education must be interwoven into every aspect of the school curriculum. More efforts should be made by manufacturers to protect the farmer in spite of himself. It is important that the operation and maintenance aspects have the highest design priority; i.e., the machine should be built around the man instead of the man around the machine. In addition to increased safety design, the farm worker must be "re-designed." More attention needs to be paid to workman's compensation laws, pre-employment physical examinations, safety training, and fitting the job to the individual. Ideally, changes in working hours, rest periods, and environmental hazards such as dust and noise could be made.³¹

Physician

The rural physician who treats farm accident victims and who renders medical care to their families is in a key position to help reduce their accidents. Printed literature can be available in the waiting rooms, and the physician should never pass up opportunities to advise and instruct safe practices.³² The rural physician must have an awareness of potential accident situations and a community interest in preventing "dis-ease." The need to protect children should be discussed with the farmer and his family. Specific measures for prevention include regular searches for physical defects, correction of those defects, and recommendations for limitations of activities beyond capabilities, especially for the senior citizen. The physician must also support his regional Agricultural Health Institute with information and help disseminate safety information as part of his local professional society. The rural physician should also be ready to minimize the conse-

quences of farm accidents, should they occur. Emphasis can be placed on pre-payment health and accident protection, welfare services, and community rehabilitation services.

Conclusions

It is a known fact that farm accidents can be decreased by an epidemiological approach. Indeed, the potential for reducing the mortality and morbidity is greater here than in cardiovascular, renal, or malignant disease. Presentation of known factors involving the agent, the host, and the environment along with proposals

for increased health promotion and specific protection provides a simple, logical way for the rural physician to approach this complex problem at the local level.

Agriculture is responsible for more occupational deaths than any other major industry in the United States. Farm machinery, falls, burns and explosions, and farm animals are common agents. Environmental factors include weather, climate, and work areas, and time of day. Accident prevention is based on the traditional "E's" of safety: education, engineering, and enforcement.

"I Wish My Hands Were as Skillful as That"

A boy in short trousers at the turn of the century, enthralled with the romance of the woods, hills and marshes, decided he was going to be a field naturalist. At sixteen he had become quite adept with scalpel and museum techniques, thanks to an older brother of his best friend across the road, who collected everything from snakes to skunks and had a museum of his own. Stammering kept the boy out of school for two years and he lived all the more in this naturalist's world, hunting alone afield and at home learning to organize, label and classify. On a fishing trip at seventeen he met a celebrated surgeon, who, leaning over and watching the boy skin a short-tailed shrew, remarked: "I wish my hands were as skillful as that." The boy's determination to be an explorer and a naturalist wavered under this compliment. The thought of being a surgeon took root. Next year at college he took biological and premedical courses, and practically committed himself to a medical future, but his parents were skeptical because of the stammering. Efforts at trying to cure the stammer developed an interest in "nerves" and psychology, which was stimulated by his professors—Parker, Munsterburg and Holt. By senior year the decision was formed to go to medical school and study neurology and psychiatry.*

Gout

Gout is the distemper of a gentleman; whereas the rheumatism is the distemper of a hackney-coachman, who is obliged to be out in all weathers and at all hours.—Lord Chesterfield

Polymyalgia Rheumatica

Report of Seven Cases

WILLIAM F. NUESSELE, M.D.
HAROLD E. MILLER, M.D.
FRANKLIN C. NORMAN, M.D.
Minneapolis, Minnesota

POLYMYALGIA RHEUMATICA is a clinical syndrome characterized by muscular pains in the girdle area and an elevated sedimentation rate, and is a frequent prodromal or concomitant feature of giant cell arteritis. Polymyalgia rheumatica is diagnosed by the clinician, often by exclusion. Giant cell arteritis is a pathological diagnosis.

Polymyalgia rheumatica and giant cell arteritis have numerous similarities. In each, the duration of the disease is usually two to four years. Clinical manifestations are comparable. Both diseases have a high sedimentation rate with few other significant laboratory findings. Either can have ocular complications including blindness. Each responds to corticosteroids. Although some believe the diseases are not related¹⁻³, there is increasing evidence, especially through temporal artery biopsy, that polymyalgia rheumatica is associated with giant cell arteritis⁴⁻⁹.

Polymyalgia rheumatica has been described frequently in European literature^{1-7,10-13} but only rarely in American.^{8,9,14,15} Although other terminology has been suggested in the past, Barber first suggested the term "polymyalgia rheumatica" in 1957¹⁰. The disease incidence has been considered⁵ commensurate with gout⁷ in the older age groups, and is felt to be a collagen disease¹.

It is characterized by rather acute muscular aching of the neck, shoulders, back, and thighs^{1,6,8-12}. There may also be headache, malaise, lethargy, fever, sweating, and anorexia. The sedimentation rate is usually elevated over 100 mm. per hour.^{5,6} There may also be slight anemia, leukocytosis, decrease in albumin and increase in alpha globulin^{1,5,6,11}. Other collagen disease and carcinomatosis may have to be excluded, although some feel that examinations for malignancy are unnecessary after becoming familiar with the disease⁵. Pathological studies of a few autopsied cases have shown little^{3,16}. Deltoid muscle biopsy has been negative^{1,11} and shoulder joint biopsy has shown only chronic inflammation².

Complications are related to ischemic effects

of associated arteritis and include brachial artery occlusion^{6,13}, Takayasu's disease (axillary artery occlusion)⁵, retinal artery occlusion producing blindness⁸ and third or sixth cranial nerve involvement producing ophthalmoplegia⁴. Symptomatic treatment includes bed rest, salicylates and phenylbutazone^{10,11,12}. Distinct subjective improvement occurs with corticosteroids and is felt to decrease vascular complications including ischemic changes of the eye and brain⁵. Polymyalgia rheumatica is usually self-limiting with a two to four-year duration^{6,10,11}, though the course may be protracted^{6,9}.

In the past few years we have had a chance to observe seven cases of polymyalgia rheumatica in our practice.

Case Report

Case 1

The first case has been previously reported.⁸ This 75-year-old woman, seen in January, 1964, had excruciating soreness of the muscles of her neck, shoulders, back, and thighs. Sedimentation rate was 110 mm. Diagnosis was uncertain and hospitalization was considered. The patient suggested the diagnosis, polymyalgia rheumatica, after studying the disease in her nephew's medical library. In July, 1964, she suddenly lost the sight of her left eye from apparent cilioretinal artery occlusion. Biopsy of a firm but non-tender temporal artery showed giant cell arteritis. Forty to five mg. of prednisone daily controlled the myalgia and sedimentation rate which fell from 70 to 30 mm. in two weeks. Although left blindness remains, she has otherwise done well. She has had three episodes of erythematous swelling of the ears relieved by tetracycline.

Comment

Polymyalgia rheumatica was diagnosed three months after the onset of myalgia. Four months later left blindness occurred from retinal artery occlusion. Asymptomatic (temporal) giant cell arteritis was then

proved on biopsy.

Case 2

Another case of polymyalgia rheumatica was diagnosed retrospectively. This 72-year-old widow was seen in 1960 with a three-month history of severe pains in the lumbar region, hips, thighs, and neck. Pain was so bad in the morning that she had to ease her way out of bed. She had a past history of unoperated cholelithiasis. Physical examination was non-contributory. Hemoglobin was 10.3 grams, sedimentation rate 108 mm. (Westergren) and white blood count 14,650 with 57% neutrophils. Serum proteins showed 1.9 grams albumin and 4.7 grams globulin. Bence Jones protein and bone marrow examinations were negative.

It was felt that the patient had an unusual collagen disease. She was treated with vitamins, hematinics, and analgesics. Although lost to follow-up, it is known that she made a slow recovery in the following years.

Comment

After other diseases were excluded, retrospective study of this patient suggests polymyalgia rheumatica.

Case 3

This 75-year-old woman was seen in July, 1965, with the abrupt onset of aching of the right shoulder, right arm, and thighs. Physical examination was negative. Hemoglobin was 12.7 grams, sedimentation rate 88 mm. and fluorescent anti-nuclear antibody positive 1:10 (not definitely significant). Temporal artery biopsy was negative. It was felt she had polymyalgia rheumatica. The patient's aching disappeared with prednisone which was continued in doses of 5-20 mg. daily. Sedimentation rate dropped to 24 mm. in three weeks. She developed a persistent blurring of her left eye. Ocular examinations showed only minimal cataracts and arteriosclerosis. Although ample doses of prednisone kept her essentially symptom-free and kept the sedimentation rate down, her course was interrupted by falls producing a fractured hip in September, 1965, and fractured arm in March, 1967.

Comment

The patient had typical polymyalgia rheumatica including myalgic and sedimentation rate response to corticosteroids. Temporal artery biopsy was negative.

Fig. 1 — Sections of temporal artery showing mononuclear infiltration and multinucleated giant cell.

Case 4

In August, 1965, this 74-year-old woman developed back and hip pain so that she had difficulty getting in and out of bed. In November she noted blurred vision, episodic vertical diplopia and mandibular pain. Physical findings were negative, except for a constricted left field of vision. The left fundus showed a few flame-shaped hemorrhages and elevation of the disc, consistent with optic neuritis. Hemoglobin was 12.0 grams and sedimentation rate 78 mm. Electroencephalogram showed mild diffuse abnormality. Cerebrospinal fluid, skull x-rays, and carotid angiography were negative. Fluorescent anti-nuclear antibody was positive 1:320. Temporal artery biopsy was negative. Impression was optic neuritis associated with arteritis. She was treated with corticosteroids.

The patient was examined at the Mayo Clinic in January, 1966. The left field of vision remained constricted and the nerve head was pale with surrounding glial tissue and pigment disturbance. They agreed with the diagnosis of temporal arteritis. Prednisone was continued. In March, 1966, the sedimentation rate was 6. After discontinuing prednisone in July, 1966, the patient had more pain in the hips and thighs. In March, 1967, hemoglobin was 12.6 grams and sedimentation rate 38 mm. No medication was used.

Comment

Although myalgia of the back and thighs preceded by two months the dominant ocular features of her disease, they were an important symptom and were relieved with corticosteroids.

*Dr. Frederick H. Lott, Pathologist.

**Attending physician, T. J. Catlin.

Case 5

In June, 1966, this 82-year-old woman began having arthralgia of the neck, back, and thighs. Indocin and butazolidin were not effective, though aspirin gave some relief. In September, 1966, she had a loss of vision in the left eye which was felt by an oculist to be vascular in origin. Medical evaluation showed diminished right and non-pulsating left temporal arteries. Sedimentation rate was 80 mm. Left temporal artery biopsy revealed giant cell arteritis (Figure 1).^{*} The patient was treated with 20 mg. prednisone daily. When seen in three weeks she had lost all her stiffness and felt much better. Her vision, however, did not improve. She could make out the figure of a picture with her left eye only. Sedimentation rate was 19 mm. The prednisone was cut to 15 and later 10 mg. daily. Myalgia was readily controlled. Her convalescence was complicated by a fall in a bus in which she suffered a fracture of her pelvis and later intervertebral disc symptoms.

Comment

Girdle arthralgia preceded unilateral blindness and biopsy-proven giant cell temporal arteritis.

Case 6**

This 74-year-old woman became ill in July, 1966, with frontal headache and stiffness and pain in the posterior neck and shoulders. She noted pain and pressure of the left temporomandibular joint; aggravated by chewing. She developed low-grade fever and left pleural effusion. Sedimentation rate was 109 mm., hemoglobin 12.9 grams, and white blood count 24,950 with 78% neutrophils. Twenty mg. of prednisone was given daily. The myalgia improved.

TABLE I
CLINICAL FEATURES IN SEVEN WOMEN WITH POLYMYALGIA RHEUMATICA

CASE	I	II	III	IV	V	VI	VII
AGE	75	72	75	74	82	74	54
MYALGIA	Neck, shoulders, back, and thighs	Neck, back and thighs	Shoulder, arm and thighs	Back, thighs, and jaw	Neck, back and thighs	Neck, shoulder and jaw	Back, & chest
FEVER °F.	99	100	99.2	100.2	98	100	100.6
Gm. Hemoglobin	12.3	10.3	12.7	12.0	11.5	12.9	11.9
F.A.N.A.	—	—	1:10	1:320	—	—	Negative
SED RATE CHANGE WITH PREDNISONE	110 to 30	108 (not treated)	88 to 24	78 to 16	80 to 19	109 to 55 and 9	108 to 38
TEMPORAL ARTERY PULSATION	Decreased	Normal	Normal	Normal	Decreased	Normal	Normal
TEMPORAL ARTERY BIOPSY	Positive	None	Negative	Negative	Positive	None	Negative
VISUAL COMPLICATIONS	Left blindness	None	Blurred vision cause unknown	Optic neuritis; constricted left field	Left blindness	None	None

When hemorrhage occurred from acute gastritis, corticosteroids were stopped. Soon there was increased myalgia, temporal pain and right hemiparesis lasting 24 hours. With resumption of prednisone she felt much better. Leukocyte count remained elevated with values from 14,600 to 23,200. Successive sedimentation rates were 55, 45, 31, and 9 mm. The patient remains asymptomatic on 10 mg. of prednisone daily.

Comment

This patient had apparent polymyalgia rheumatica with symptomatic temporal arteritis complicated by probable cerebrovascular insufficiency producing transient hemiparesis.

Case 7*

This 54-year-old woman was seen first in 1965 with exhaustion, chills, fever, abdominal pain, and weight loss. Events in her past health included tonsillectomy, appendectomy, hysterectomy, cholecystectomy, thyroidectomy for hyperthyroidism and subsequent hypothyroidism. Physical examination showed no abnormalities. During hospitalization her temperature was 99.6 to 100.6 F. X-ray survey was negative. Hemoglobin was 11.9 Gm., sedimentation rate 108 mm., serum proteins normal except for a slight increase in alpha globulins, and T-3 9.6% (normal range 10.3 to 14.3%). LE prep, bone marrow, and fluorescent anti-nuclear antibody tests were negative. Retroperitoneal sarcoma was considered but abdominal exploration was negative. Peritoneal biopsy showed chronic inflammation and fibrosis. The patient was maintained on supplemental thyroid.

She continued to have low-grade fever and began having headaches, back pain, and chest pain. Sedi-

mentation rates varied from 40 to 80 mm. In November, 1966, a daily dose of 20 mg. of prednisone was started. She felt better and the sedimentation rate dropped to 10 mm. She discontinued prednisone and her aching returned in the head, neck, arms, and legs. Sedimentation rate was 37 mm. At this time biopsy of a normally pulsating temporal artery was negative. Prednisone was resumed and she has remained symptom-free.

Comment

Abdominal symptoms initially dominated her disease. Myalgia consistent with polymyalgia rheumatica occurred later. There was favorable response of myalgia and sedimentation rate to prednisone.

Discussion

Seven cases of polymyalgia rheumatica are reported. All were women, ranging in ages from 54 to 82 years. Sedimentation rates varied from 78 to 110 mm. When followed, sedimentation rates decreased markedly on prednisone. Three had definite visual complications. Two of five with temporal artery biopsy showed giant cell arteritis. Temporal arteritis is known to be patchy in "skip" areas so that a negative biopsy does not exclude the disease⁹. Two patients had falls producing serious fractures. Table 1 reviews the clinical features. The features in reported polymyalgia rheumatica are summarized in Table 2. These

include the predominance of women, older age, high sedimentation rate, eye complications, and numbers showing giant cell arteritis on temporal artery biopsy.

Summary

The clinical syndrome of polymyalgia rheu-

matica is reviewed and seven cases reported. It would appear that polymyalgia rheumatica is a frequent concomitant feature of giant cell arteritis in a systemic collagen disease. Both diseases should be treated with corticosteroids to decrease ischemic complications including blindness.

Medical Men on Postage Stamps

Leon Calmette (1863-1933) was a French bacteriologist and co-developer with *Camille Guérin* (1872-1961) of the tuberculosis vaccine BCG (*Bacillus-Calmette-Guérin*). Calmette also introduced a serum for snake bite and described the ophthalmic tuberculin reaction. Among several countries issuing postage stamps in commemoration of Calmette's and Guérin's joint achievement were France in 1948, Belgium in 1953, and St. Pierre Miquelon in 1963.

Nicolas Gutierrez (1800-1890) was a Cuban anatomist, surgeon and medical writer, who started Cuba's first medical organ, *El Repertorio Medico Habanero*. Recognition was awarded his pioneer work in medical journalism by the issuance of a Cuban postage stamp in 1940.

Remedies for Broken Bones

For broken bones, a sovereign remedy is the ashes of the jaw-bone of a wild boar or swine: boiled bacon, too, tied round the broken bone, unites it with marvellous rapidity. For fractures of the ribs, goats' dung, applied in old wine, is extolled as the grand remedy, being possessed in a high degree of aperient, extractive, and healing properties.

Thinking is more interesting than knowing, but less interesting than looking.—Goethe

How Long Can One Live*

One side of the longevity problem is determined by social factors. But there is another side to it, which is based on biological laws.

A great many men live to be ninety, a hundred, and even more. The greatest number of people over a hundred live in the Soviet Union. The 1926 census placed them at about 7,000. Fifty-five of them lived in Moscow. Bulgaria was second with 158. There were 86 in Germany, 58 in Sweden, and 51 in Italy. In Norway, which is to all appearances a country of strong men and women, there were only 35 people of a hundred and over.

In 1937 the Ukrainian Institute of Clinical Physiology found several old men aged 130, 135, and 142 in Abkhasia. In 1936 mountaineer Khapara Knut died in Abkhasia's Ochemchiry District at 155. He had been the oldest man in the world. In August 1949 Vasily Tishkin, a Stavropol collective farmer aged 144, took a holiday at the Central Trade Union Council's Sanatorium No. 22.

Hundred-and-forty-eight-year-old Mahmud Bagir ogly Eivazov works at the Komsomol Collective Farm in Azerbaijan. In March 1956, when he celebrated his 148th birthday, he was awarded the Order of the Red Banner of Labor for his meritorious work in collective farming.

But many people live no longer than 80-85 years. Many more live only 60-70 years. And quite a few die at 45 and 50.

It is natural to ask how long a man could really live. . . . Buffon, who lived in the 18th century, proposed an original method of calculating the answer. He determined how long domestic animals grow by watching the growth of their bones. That was easy. An organism is full-grown when its bones stop increasing in length. A dog, Buffon established, grows two years, a cat—18 months, a cow—four years, a horse—five, and a camel—eight, etc. He then divided the life span of each animal species by its period of growth. This yielded a mean figure of six, leading him to the conclusion that the life span of any higher mammal, including man, is five-six times longer than its period of growth. According to him, therefore, man's normal physiological life span is 150 years, or six times his period of growth, which lasts about twenty-five years.

*L. Fridland, M.D.: *The Achievement of Soviet Medicine*, 1961, edited and translated from the Russian by W. Horsley Gantt, M.D.

Pioneer Anesthesia with Cold

Hippocrates of Cos, the great physician who was born about 459 B.C., used his considerable powers to find effective ways of easing pain. He is said to have used *cold* as a means of producing insensitivity. He would numb a limb by packing it in ice or snow before performing the operation.

Pain relief by chilling was reintroduced in 1646 by the Neapolitan physician and anatomist, Marco Aurelio Severino. The technique used was described by Thomas Bartholin of Denmark in his book, *The Medical Use of Snow*.

"Before employing cautery on wounds in various parts of the body, apply snow to dull the sensation. Severino had to apply the medication in narrow parallel lines; after a quarter of an hour the feeling would be deadened and the part could be cut out without pain."*

Bacteremia and Candida Septicemia

Review
of
185 Cases
During
A
Four-Year
Period

WILSON SALTER, M.D.*
HORACE H. ZINNEMAN, M.D.**
Minneapolis, Minnesota

SINCE THE INTRODUCTION of antibiotics the number of serious staphylococcal infections, particularly those occurring within hospitals, has greatly increased.¹⁻³ More recent attention has been drawn to the increase in gram-negative bacterial infections and to systemic mycoses.^{1,3-6} It seemed worthwhile to review the cases of bacteremia and fungemia seen at Minneapolis Veterans Hospital during a four-year period with regard to underlying host factors, source of infection, etiologic agent and the role of antibiotics and other chemotherapeutic agents in the occurrence and course of these infections.

Materials and Methods

This retrospective study encompasses 185 patients with proven bacteremia or fungemia over the period from January 1, 1962, through December 31, 1965. Positive blood cultures obtained prior to death and recorded in the files of the bacteriology department of this hospital were assembled and the corresponding clinical charts reviewed. Some records of patients with positive blood cultures were not obtainable due to improper identification, misplaced records, etc., so that the study does not represent the total experience for the stated period. The patients were predominantly white males ranging from 22 to 92 years and included two Negroes and two females. The average age was 59 years. The yearly distribution of cases over the time period is shown in Table 1. Blood cultures were performed by a closed technique using Trypticase soy broth media.† Fifteen to 20 ml. of venous blood were collected in two vacuum bottles, one anaerobically and the other with aseptically filtered air. All cultures were incubated for a minimum of five days and for a longer period, extending to 21 days, if clinically indicated. After 48 hours all cultures were subcultured on blood agar. The incidence of

*Fellow, University of Minnesota Medical School.

**Associate Professor, University of Minnesota Medical School.

Requests for reprints should be addressed to: Horace H. Zinneman, M.D., Veterans Hospital, 54th Street and 48th Avenue South, Minneapolis, Minnesota 55417.

contamination has been less than 0.5 per cent.

Results

The number of organisms isolated each year is shown in Table 2.

Most Frequent Organism

There was a persistently high incidence of coagulase-positive staphylococci and *Escherichia coli* throughout the four-year period (Tables 2 and 3). In 1965 *Candida* accounted for 11.9 per cent of all isolates, but only for 4.6 per cent of the total number during the four-year period (Tables 2 and 3). *E. coli*, *Proteus* and *Klebsiella enterobacter* were the most common gram-negative organisms during the entire period (Table 3).

Source of Infection

Table 4 reveals a difference in source of infection between fatal and non-fatal bacter-

emias. The *urinary tract* was the most common source in non-fatal bacteremias, followed by the *respiratory tract*; whereas the reverse was true for fatal bacteremias.

Discussion

The preceding data show a significant increase in yeast septicemia. Nine of 10 cases occurred in the last year of the review, 1965. During the four-year span, *E. coli* and coagulase-positive staphylococci were the most common pathogens; however, in 1965 the incidence of *D. pneumoniae* was the highest. Malignancies accounted for 37.7 per cent of the underlying diseases in fatal cases and for 28 per cent in those surviving the bacteremia. Lymphomas and leukemias accounted for 35 per cent of the malignant processes in the fatal cases and for 17.9 per cent in those surviving. It is well known that patients with granulocytic leukemia have a poor leukocytic response to infection, and lymphatic leukemia is often associated with immune globulin deficiency.⁷ These factors greatly influence the course of any bacterial infection. Gastrointestinal and biliary tract disease was present in 14 of 53 patients who succumbed to their bacteremia (26.4%) and in 22 of 132 patients who survived (16.6%). Bacterial endocarditis was slightly more than twice as common

in fatal (7.5%) than nonfatal cases (3%). The most common source of infection for all bacteremias was the urinary tract (56 patients or 30.8%). Genitourinary tract disease was more prevalent in those surviving their bacteremia: 23 of 132 patients (17.4%) as compared to seven of 53 patients (13.2%) with fatal cases. *Proteus* was a common urinary pathogen in this study, yet it caused only two deaths in a total of 18 bacteremias. Coagulase-positive staphylococci and gram-negative organisms appear to be the major agents of bacteremia.^{1,2,4} Together they accounted for 121 of 196 isolates or 61.6 per cent. Of this total, gram-negative organisms accounted for 42.3 per cent and staphylococci 19.3 per cent. *E. coli* was the most common gram-negative isolate (34.9%). Finland et al.² compared bacteremia at Boston City Hospital in the pre-antibiotic era with the years following introduction of penicillin and broad-spectrum antibiotics. Prior to antibiotics, the pneumococcus was the most frequent pathogen. Hemolytic streptococci declined following the introduction of sulfonamides and penicillin, but the

incidence of Group D streptococci increased and persisted. The incidence of *Staphylococcus aureus* increased four-fold from 1935 to 1957, constituting the most significant increase. The pertinent findings of the present study concern bacteremias due to staphylococci and gram-negative rods as well as the emergence of another type of blood stream infection: *Candida* septicemia. These three groups of bacteremia merit a more detailed discussion.

Staphylococci Infections

11 patients cultured 2 different organisms.

Total percent of patients dying subsequent to bacteremia = 27.

Note that coagulase-positive staphylococci represented slightly more than nineteen percent of the total number of isolates and had a mortality of 37.5. The single salmonella bacteremia is not included in the gram-negative bacteremias.

sequent to a coagulase-positive staphylococcal bacteremia. One half of the fatal cases had malignant diseases and slightly more than half had acquired the infection while in the hospital. Table 5 reveals some of the circumstances which influenced survival following staphylococcal septicemia. The five cases of coagulase-negative staphylococcal septicemia will not be dealt with here except to note that the two fatal ones had underlying aortic valve disease.

The lack of consistency in antibiotic therapy complicates the interpretation of the causes of mortality. Waisbren⁸ reports an over-all mortality of 64 per cent in 100 cases of staphylococcal septicemia, Smith and Vickers⁹ 71 per cent, Hassal and Roundtree¹⁰ 58 per cent, Allen et al.¹¹ only 27 per cent. This concerned a group of 22 cases which were treated with methicillin. Kucers and Bennett¹² report 36 per cent mortality in 33 patients in whom chloramphenicol and penicillin were the initial basic treatment. Penicillin and chloramphenicol also formed the initial therapy of the majority of patients in this study and was associated with a mortality of 37.5 per cent. In view of the increasing resistance of staphylococci to chloramphenicol, this regimen does not appear to be preferable. Methicillin and some of the newer semisynthetic penicillins have a narrow range of activity, and relatively large doses are needed for penicillin-sensitive strains.

Prophylactic Administration of Antibiotics

The prophylactic administration of antibiotics or combinations of antibiotics frequently results in infections and bacteremias due to organisms which are highly resistant to therapy.^{13,14} In this study, 11 of 38 patients received antibiotics prior to emergence of staphylococcal bacteremia; in the five fatal cases the antibiotics used were either penicillin or chloramphenicol alone or combined.

There has been a growing awareness of increased numbers of hospital-acquired staphylococcal infections.^{1,15} In this study, the initial infection of eight of the 14 fatal cases of staphylococcal bacteremia occurred within the hospital. Extremes of age, debilitating illnesses such as diabetes mellitus, malignancy, hypersensitivity diseases and skin disease have been noted to predispose patients to staphylococcal septicemia.^{8-10,12,15,16} Seven of the 14 fatal cases in this study had a malignancy and two others had diabetes. Rogers¹ study supports the impression that antibiotics have not dramatically altered the risk of infection in seriously ill hospitalized patients. He notes that 93 per cent of all bacteremias arising in the period of 1957-59 occurred in patients with serious underlying disease, whereas only 40 per cent were seen in similar patients in the era of 1938-1940.

Portal of Entry

The most common portal of entry for *Staphylococcus* has been the skin.^{8,17,18} This accounted for slightly over 18 per cent or seven of 38 patients in this review as compared with 22 per cent in Waisbren's series. A high incidence of staphylococcal infections occurs postoperatively. Cluff and associates¹⁸ noted that wound infections account for 70 per cent of acquired staphylococcal disease, the majority after laparotomy. In this study five of 38 or 13 per cent of the patients had a bacteremia following postoperative wound infections. Staphylococcal septicemia followed the use of polyethylene intravenous catheters in 12 of 86 of Hassal's patients.¹⁶ A single case has been reported previously from this hospital;¹⁹ 13 others, where an intravenous polyethylene catheter was the probable source of invasion, are also contained in this group of 196 bacteremias. In this study the respiratory tract

TABLE 5
Bacteremia Due to Coagulase-positive Staphylococci

Fatal Cases	Percent	Survivors	Percent
1. Antibiotics prior to bacteremia	5/14 35.7	6/24 25	
2. Acquired in hospital	8/14 57.1	8/24 33.3	
3. Malignancies	7/14 50	2/24 8.3	
4. Chemotherapy, steroids, x-ray	5/14 35.7	2/24 8.3	

was a source of staphylococcal sepsis equal to the skin.

In general, severe staphylococcal infection and bacteremia correlate with increasing age and debility, increased and protracted use of intravenous therapy, emergence of resistant strains of staphylococci under inadequate antibiotic cover, and use of corticosteroids, antimetabolites and alkylating agents.

Gram-negative Rod Infections

The significance of gram-negative bacteremias is obvious since they represented 42.3 per cent (83 isolates) of 196 isolates. McCabe and Jackson found a five-fold increase over an eight-year period (1951-1958). Finland and associates² observed a marked increase in gram-negative bacilli between 1935 and 1957. *E. coli* increased significantly following the introduction of antibiotics. There was a partial decrease in incidence after 1947, about the time broad-spectrum antibiotics came into general use. *Proteus* closely followed *E. coli* along with *Enterobacter* and *Pseudomonas aeruginosa*. At this hospital, *E. coli* represented 34.9 per cent of all gram-negative bacteremias, followed by *Proteus* 21.5, *Klebsiella-enterobacter* 19.2, *Paracolon* 12 and *P. aeruginosa* 10.8 per cent. A high fatality rate was seen for bacteremias of *P. aeruginosa* (88.8%) and *Klebsiella-enterobacter* (37.6%). McCabe and Jackson⁵ found a 69-per cent fatality rate with *P. aeruginosa* and mixed infections. Their study showed a significant difference between the two sexes in regard to age. More than half were seen in male patients over the age of 50, while in females one half the cases occurred below the age of 50. There was only

one woman in this group of gram-negative bacteremias; the average age of males was 65.

Malignant Disease

Eleven of 26 deaths occurred in patients with underlying malignant disease. Three had chronic lymphatic leukemia, one lymphosarcoma and one pancytopenia. Thus, five of 11 malignancies involved the hematopoietic system, again emphasizing its importance in infection.

Table 6 summarizes the mortality, the most frequent source of bacteremia, the organism most frequently responsible and the incidence of hypotension in this study and compares it to three other reviews of gram-negative bacteremia.

Genitourinary

The urinary tract was the source in 40 of 83 gram-negative bacteremias (48.1%). In 13 instances it followed a procedure involving the genitourinary tract, i.e., cystoscopy, transurethral resection of the prostate, suprapubic prostatectomy, dilatation of urethra or plastic procedures of the bladder. The frequent occurrence of gram-negative bacteremia following genitourinary tract surgery and catheterization has been recognized by others²⁰⁻²⁴; it occurs in 20 to 54 per cent of reported cases.^{22,23,25} *Proteus* and *E. coli* were the agents, each in five patients. Bacteremia followed cystoscopy in five instances and transurethral resection of the prostate in three. The gastrointestinal-biliary tract was the source of infection in 11 instances (13.2%) and the respiratory tract in seven cases (8.4%).

TABLE 6
Gram-negative Bacteremia as it Appeared in Four Independent Studies

Authors	No. of Patients	Percent Mortality	Most Frequent Organism		Incidence of Hypotension	Source of Bacteremia

*MVAH = Minneapolis Veterans Administration Hospital

In Martin's²⁰ review of 303 gram-negative bacteremias the urinary tract was the source in about 50 per cent, the gastrointestinal tract in 15 per cent and the biliary tract in 10 per cent. Respiratory tract infection with *P. aeruginosa* was increased. In the present review, *P. aeruginosa* bacteremia in four of nine patients had the source of infection in the respiratory tract. Twenty-nine patients had a drop in blood pressure of 90/60 mm. or lower during the course of their gram-negative bacteremia. Table 7 gives the incidence and death rate for each organism.

TABLE 7

Total	29/82		17	

Shock

Shock occurred in slightly over 35 per cent of patients. More than half of the episodes (58.6%) resulted in the death of the individual. In Hodgkin's and Sanford's²¹ series shock occurred in 38 per cent with a mortality of 74 per cent. Forty per cent survived where the systolic pressure did not fall below 80 mm.; below this level, only 11 per cent of the stricken individuals survived. In this study, hypotensive episodes in *E. coli* or *Proteus* bacteremia had a much more favorable course than in pseudomonas, paracolon or enterobacter bacteremia. In general, hypotension in the former group was of shorter duration, and the response to therapy was more prompt than in the latter.

Multiple Antibiotics

Table 8 lists 19 patients who received antibiotics within a week of the bacteremia. It also lists the underlying disease, organism cultured,

antibiotic sensitivities by standard disc method, occurrence of hypotension, treatment following culture and outcome.

Thirteen of the patients had been receiving multiple antibiotics and two were also given adrenocortical steroids prior to the onset of bacteremia. Severe chronic underlying disease was present in the majority of patients (four with malignancies, three with diabetes, three with ulcerative colitis and two with Laennec's cirrhosis). Mixed cultures were found in patient No. 3, and patient No. 8 had two different organisms cultured, separated by 20-day intervals. Patient No. 12 entered the hospital as a transfer from private care and had received antibiotics unknown to the staff of this hospital prior to entry. This patient experienced two episodes of *Enterobacter* septicemia with moderate hypotension during the second episode. Patient No. 19 had chronic myelogenous* leukemia and pyelonephritis. He suffered two episodes of *Proteus* septicemia separated by a four-month interval and had received multiple, apparently appropriate, antibiotics prior to both. Patients 16, 17, and 18 experienced septicemia with highly resistant strains of *P. aeruginosa* while receiving multiple antibiotics. Petersdorf et al.²⁶ have noted that pseudomonas septicemia is likely to follow antibiotic administration.

Stamey²⁷ has stressed urine concentrations of an antibiotic as a measure of adequate therapy of urinary tract infection. He found that sterilization of the urine, as well as ultimate cure, was directly dependent on bactericidal urine level of the antibiotic, independent of the concentration in serum or plasma. Since gram-negative bacteremia so often originates from the urinary tract, this becomes an important factor. However, Ronald et al.²⁸ contend that agents which attain high antibacterial concentrations only in the urine should not be used in treatment of patients suspected of having renal parenchymal involvement. He notes that patients with chronic bacteriuria who relapse with the same strain usually have infection in the kidney, whereas reinfection with new strains is more common in patients with bladder bacteriuria. When relapses with the same strain occur, a successful course of therapy can be attained with antibiotics having bactericidal

levels in both blood and urine, such as ampicillin.

Candida Septicemia

Candida albicans was established as the etiologic agent of thrush in 1846. Later, Virchow showed that it was capable of deeper penetration, after he found it in the submucosa of the esophagus.²⁹ It was once believed to be the only pathogenic member of the genus, but Schurtleff,³⁰ Richart and Dammin³¹ have found *Candida tropicalis* capable of producing disseminated disease as well. This species causes disease indistinguishable from that caused by *C. albicans*. In this study, six

cases of *C. albicans* septicemia, three *C. tropicalis* and one unidentified yeast were cultured from the blood of 10 patients. In four the *Candida* was either directly responsible or a major contributory factor to the demise of the patient. In two others, it may have been a contributing factor. Table 9 summarizes the age, sex, underlying disease, organism, antibiotics used prior to the fungemia, clinical and in some cases autopsy findings.

Five patients had a neoplasm and three were diabetics. Patients 1-4 were thought to have died as a result of the *Candida* sepsis. Nine of the 10 received broad-spectrum antibiotics prior to or during the septicemia. Eight received

chloromycetin and seven penicillin; none were treated with Amphotericin B. Five patients developed signs of renal failure and four hypotension.

Hematopoietic Disease

It has been emphasized that patients with

disseminated fungal infections often are suffering of a primary hematopoietic* disease such as leukemia, lymphoma, aplastic anemia and related leukopenic disorders, or are receiving steroids, alkylating agents or antimetabolites as well as broad spectrum antibiotics.³²⁻³⁴ In this study, all five neoplasms occurred in the

gastrointestinal tract; three other patients had non-malignant disease of this system, and none received steroids, alkylating agents or anti-metabolites prior to the *Candida* septicemia.

Suppressing Bowel Flora

Harrell,³⁵ Braude and Rock³⁶ noted that acute disseminated candidiasis frequently develops against a background of continuous antibiotic therapy during the course of a protracted debilitating disease, particularly when normal bowel flora is suppressed. In experiments, certain broad-spectrum antibiotics (tetracycline and aureomycin) have been shown to enhance the virulence of *C. albicans*.³⁷ In a review of 48 cases of disseminated candidiasis, Hurley²⁹ noted that antibiotics had been given in 43; however, there was also a history of serious underlying disease. She concludes that antibiotic therapy cannot be the sole predisposing factor to fatal moniliasis since the incidence of fatal fungus infections has not increased since the introduction of antibiotics in England where her study was performed. But Seelig⁶ and Zimmerman³³ in this country claim an increased incidence. The present study would tend to support them as well as the claim that serious primary disease is invariably present.

Tissue Damage

The gastrointestinal tract has been stressed as a source of systemic candidiasis.^{6,31,36} Braude and Rock³⁶ noted that mucosal injury in patients on antibiotics was the usual setting for the dissemination of *Candida*. Eleven cases of 31, reported by Louria,³⁸ had severe pharyngeal or gastrointestinal lesions which led to dissemination. This was the likely source in four of our patients. Another source is provided by protracted intravenous therapy, especially with use of a polyethylene catheter. Case No. 4 had a well documented focus on the tip of the indwelling catheter from which *C. albicans* was cultured. A similar set of circumstances was suspected in three others.

Renal insufficiency during the course of systemic candidiasis has been encountered experi-

mentally and clinically. Richart and Dammin³¹ described two cases of disseminated *C. Tropicalis* which resulted in renal failure and central nervous systemic depression. The organism was found most often in the yeast phase in early tubular lesions. Hyphae* were noted to form in the periphery of lesions of experimental infections. Little inflammatory response was found at autopsy unless tissue necrosis had been produced.

Shock following intravenous injection of *Candida* has been produced in dogs;³⁹ it was more profound with intact cells than with disrupted cells and supernatant. Three patients in this study, Nos. 1, 2, and 4, had definite evidence of endotoxin-like shock manifested by oliguria, hypotension, fever, mental disturbances and progressive renal failure.

None of these ten patients received specific antifungal therapy. The problem of treatment with Amphotericin B is often compounded by the presence of compromised renal function. The effectiveness of Amphotericin B has been demonstrated by Louria et al.,⁴⁰ but prolonged high plasma concentrations are necessary. The prophylactic use of antifungal antibiotics, such as Nystatin with antibacterial agents, has been shown to be effective in reducing the candidal counts in the stools, although less effective in reducing the overgrowth in sputum.³⁰ Seelig⁶ points out that this is not unusual since direct contact of the antifungal agent with the *Candida* is necessary for antifungal activity. Increased awareness of the seriousness of the problem may prompt early intervention. The prophylactic use of oral antifungal agents might be considered for debilitated patients who are receiving prolonged antibacterial therapy.

Conclusion

Bacteremias with coagulase-positive staphylococci and gram-negative bacteria produced the majority of deaths in this study and were often superimposed on a background of neoplastic disease, especially of the hematopoietic system. Other chronic debilitating diseases of major significance in fatal cases are diabetes mellitus, gastrointestinal-biliary tract disease and chronic lung disease. In non-fatal bactere-

*See Test Your Word Score Page 1513.

mia, genitourinary tract disease was a common underlying condition and source of infection. An increasingly more frequent portal of entry is the intravenous polyethylene catheter. Shock during the course of bacteremia was associated with a mortality of almost 60 per cent. *P. aeruginosa* and *C. albicans* were found to complicate malignant disease, produce shock and follow antibiotic therapy in a high percentage of patients harboring these pathogens. The high death rate of *Candida* septicemia in this study bears emphasis and occurred in patients

with non-malignant disease of the gastrointestinal or biliary tract and with diabetes mellitus. Five of 10 patients suffering *Candida* septicemia had a malignant lesion; however, these patients survived the sepsis. Progressive deterioration in renal function and mental status and hypotension were manifested by all patients dying from yeast septicemia and should be considered an indication for more vigorous therapy. There has been a striking increase in the incidence of *Candida* septicemia within the last two years.

How To Mount

My first ambulance call was set for the evening of June 30th, and they made it a transfer of a patient from Beth Israel Hospital up to Bellevue Hospital. I telephoned my family that I had received my first orders, and was ready in my uniform with the ambulance bag in my hand when Dick Bateman who was the driver on duty backed the ambulance in. He quickly jumped down and ran around to me saying: "Doc, I want to show you a trick or two, how to get on the bus, if you want me to." Did I want him to! Good, kind Dick Bateman; in a five-minute demonstration he showed me just what and what *not* to do, and I have been eternally grateful to him. He showed me how to sit on the seat and with one quick bounce swing both feet up from the step of the ambulance over the tailboard and so into the "bus." He made me rehearse this three or four times and I soon found it was not unlike mounting a horse. When once you were on the seat, a sense of balance helped you to keep it and there were two solid leather hand straps that I gratefully relied on at first. I have always felt that this careful, thoughtful instruction gave me a good start and as soon as I had the proper technique, I never knew what physical fear was in our roughest and hardest driving.*

*Emily Barringer, M.D.: *Memoirs of a Lady Ambulance Surgeon*, Bowery to Bellevue, 1950.

Mr. President—Your Health***James Madison (1751-1836)**

Our fourth President, James Madison, belonged in that category of medical paradoxes whose longevity belies their constitutional frailty.

Though never robust as a child, young James enjoyed outdoorsmanship; he rode horseback and hiked in the woods and fields, observing birds in particular. Communion with nature, however, did not preclude a predilection for study, which took him through a four-year college course at Princeton in slightly over two years.

During his teens and early twenties Madison complained of voice impairment, a functional handicap that prevented his public speaking until he was 30. Correlative with his vocal weakness was "a constitutional liability to sudden attacks of the nature of epilepsy," doubtless hysteric rather than neurogenic in origin, but which undermined his morale and prevented his demonstrating his inherent ability.

Because he was shy and sensitive Madison's own assessment of his constitutional stamina was low, if not depreciatory. Despite his good fortune in escaping such prevalent diseases as malaria, tuberculosis, smallpox, and yellow fever, he was neurotically convinced that his body harbored some insidious malady, an obsession he finally overcame only with prodigious determination.

Physically Madison was always frail in appearance, short of stature, and slight—never weighing over 100 pounds to his five feet, four to six inches. With age his complexion became sallow and his eyes blepharitic. Though unimpressive physically, he was withal ever a gentleman of good breeding and a patriot of statesmanlike dimensions.

From his middle years on, Madison was plagued with biliousness and arthritis, for neither of which medical science offered much relief. Of his disabilities his wife once wrote to a friend:

"My dear Husband is still confined to his bed. In addition to a disabling rheumatism throughout the winter, he has had a bilious fever, which has reduced him so much that he can only walk from one bed to another. I never leave him more than a few moments at a time, and have not left the enclosure around our house for the last eight months on account of his continued indisposition, concerning which friends at a distance have rec'd but too favourable reports. Our Physicians have advised the Warm Springs for Mr. Madison, and we hoped to have taken him there, but as he could not travel unless conveyed on his bed, we dare not think of it at present."

Had Madison lived in the twentieth instead of the eighteenth century gall-bladder surgery and sulfa drugs might have relieved his chronic cholecystitis and progressive arthritis. However, it was not until he reached his early eighties that arteriosclerotic deterioration set in, impairing both his vision and his hearing. He just began to fade away, growing thinner and weaker until one morning he was found dead in his bedroom sitting in front of his untouched breakfast tray.

In spite of the numerous functional ailments of his earlier life and the organic pathologies of his later years Madison had reached the august age of 85 years, three months, and 12 days.

Tell me to what you pay attention and I will tell you who you are.—Ortega Y Gasset

Alcoholism

The problems of modern medicine are creating moral, scientific, and ethical implications which medicine and theology must consider. They must develop for society certain guidelines by which modern medicine can move into these new areas.

The first of these is that of the ethical implications on organ transplant. It is more than the laboratory's technical skill and procedure which can be either successful or not successful in the taking of an organ from a living being and transplanting it into another living being. It involves many ethical questions and decisions which must be discussed, because each patient is a patient unto himself, and the families create circumstances which make us approach patients in different attitudes of mind. Joseph E. Murray, M.D.*, has said in "The Unrelated Donor:"

"Justification even for the use of a cadaveric kidney or a 'free' kidney is not automatic just because the prospective recipient is otherwise doomed to die. . . . All the more difficult to justify is the use of living volunteer donors. Although chemical suppressive agents may be effective temporarily, many questions remain unanswered. . . . 'The potential dehumanizing abuses of a market in human flesh' is a phrase used by Lederberg (in MAN AND HIS FUTURE). Although admitting that his attitude may be construed as an 'alarming or ungracious reaction to the gift of life,' he warns against misguided medical progress in the name of humanity. Physicians removing intact organs from healthy donors without a conscientious concern for the problem of better procurement may be likened to the old lumber barons felling trees indiscriminately. . . . To our knowledge no healthy living donor has yet been an operative fatality, yet fatal operative complications are always possible. As physicians motivated and educated to make sick people well we make a basic qualitative shift in our aims when we risk the health of a well person, no matter how pure our motives. To relieve ourselves of this responsibility we must strive for better organ procurement so that the day will come when even identical twins will not require a living donor."

We are dealing not only with the kidney, for I know the day will come through research, understanding, and knowledge in medical science when we will be in the position to transplant all types of human organs, as well as install plastic and artificial ones. Recently at a College of Surgeons Meeting, a physician, speaking on the work which is being done concerning the plastic heart, called attention to the idea that within three or five years it was going to be possible to place a plastic heart inside the patient, replacing his present damaged heart. The question that might then be asked from a moral, ethical implication is: what is life?

In our modern-day society we consider that death prevails when the heart ceases to beat. Oft times we go to extreme measures or artificial and mechanical ways to keep the heart beating. The patient appears alive; though in any reasonable sense of mentality, ability to move, to love, or to receive love, he no longer exists. When the time comes that we are able to place a plastic heart inside the chest cavity of the individual, then the question might need be asked: when does this patient's life cease? Theologically it is an age-old question—what is life? But with the advances of modern medicine, these are areas where only the theologian and the physician can honestly give guidelines to society. Perhaps we are going to need other ways of measuring life and death.

"The bioelectric activity of the living brain is silenced by anoxia which soon produces cerebral death. Respirators and heart stimulators can maintain the look of life in the face of death while agonizing and expensive prolongation of false hope continues for all concerned. When the brain is so comprised, the EEG can signal the point of no return, although the

Continued

*Assistant Clinical Professor of Surgery at Harvard Medical School.

cardiovascular system continues to respond to supportive therapy that produces a respectable ECG. Supportive efforts should be continued only so long as the brain shares physiological response together with heart and lungs. Adequate experience has been analyzed to show that competent application and interpretation of the EEG should gain medical approval for legal pronouncement of human death."*

There are no easy answers. We must confront ourselves as physicians and as theologians in dialogue and in communication, in consultation, in agreement and in disagreement, for we are not dealing with ourselves; we are dealing with our patients and our parishioners who are whole persons.

The two professions of medicine and religion must become deeply concerned with the life and the total health—of every individual. From their collective judgment will come the means for providing the most effective care and treatment of the patient as a whole man. This is the new concept. The two forces, medicine and religion, with one goal—knowing full well that illness may be organic, may be spiritual, may be emotional, or may be social—must solve the dilemma. This, then, is our one goal—total care.

Nodular Lesions of the Leg

ALTHOUGH THERE may be no specific "Nodule of the Leg" syndrome, the condition is common enough to be a challenge to many disciplines of medicine. For the female adult population with the overexposure that their lower extremities must endure, disfiguring nodules are disturbing, and care is mandatory for cosmetic reasons if for no other. The majority of patients with this condition ultimately find their way into the office of the dermatologist. Most of these conditions are only part of a generalized dermatological disease; but because of involvement of the leg where their presence is more obvious and therefore more unsightly, there is greater concern on the part of the patient.

Aside from the dermatological problems such as lichen planus,* psoriasis and localized dermatoses, there are many leg nodules that are of significance as monitors of systemic illness. Erythema nodosum certainly must be the most significant of the painful type of leg nodules. Their relationship to tuberculosis and beta hemolytic streptococcus disease has been known for many years. However, more recently we have learned of their presence in association with such less well known entities as histoplasmosis, coccidioidomycoses, sarcoidosis and psittacosis, to mention only a few. Erythema nodosum may also be seen with some drug reactions such as bromides, iodides and sul-

fanilamides. Erythema multiforme with its varied types and presentations is a less frequent cause of inflammatory leg nodules but may be present in many of the situations that are associated with erythema nodosum. Weber-Christian syndrome as one of the causes of inflammatory leg nodules is of more recent description, as well as the nodular fat necrosis of acute pancreatitis. These and other causes of leg nodules are described in the July issue of MINNESOTA MEDICINE by Dr. Carl Laymon.**

Pulmonary osteoarthropathy as the monitor of certain lung conditions can present as erythematous nodular lesions of lower legs and feet. Localized myxedema is a relatively rare complication of Graves' disease and is seen in some patients with severe exophthalmos. This condition usually occurs in the outer portion of the lower third of the legs and presents as a non-pitting, painless swelling which may have a purplish, reddish color. Necrobiosis diabetorum is manifested by firm, yellowish plaques present usually on the anterior surface of the lower leg.

Recognition of urticaria, thromboses of varicosities and insect bites are no great problem. However, when multi-hued nodules, indurated or soft, small or large, discrete or diffuse, bilateral or unilateral, present themselves, dermatological consultation is sought in many instances. The dermatologist can often point to a systemic etiology and provide the needed tip to solve a perplexing diagnostic problem.

DUAL PROBLEM IN PEPTIC ULCER

Relief of hyperacidity is still a primary goal in the treatment of peptic ulcer. And antacids are the most widely used means of achieving this relief. But antacids alone cannot influence the distention and bloating which so often add to ulcer distress.

THIS IS WHY MYLANTA® PROVIDES:

the two most widely used antacids—magnesium and aluminum hydroxides—to help secure rapid acid neutralization with little chance of laxation or constipation;

PLUS

the defoaming action of simethicone—to help relieve the painful gas symptoms which often accompany peptic ulcer.

Mylanta®

antacid therapy plus an added benefit

nonfatiguing flavor/smooth pleasant texture; both assure patient cooperation during long-term therapy.

Food Allergy

ALLERGY to foods has been observed for many centuries. The real incidence of food allergy is unknown, but that it is common cannot be denied. Perhaps the majority of persons have at one time or another had occasional or mild complaints referable to a specific food, usually infrequently eaten and easily detected. In such conditions as gastrointestinal complaints, headaches, urticaria, asthma, rhinitis, insufficient importance is given to food allergy.

Age is a factor bearing on the incidence and possibility of food allergy. In infants, foods are common allergens. In adults, although other types of allergens seem more important, foods still play a role in allergic manifestations. In asthma or rhinitis food will frequently be an additive factor to the inhalants as a cause of symptoms. Removing the offending foods may give relief even though other allergens are also involved, and vice versa. Hyposensitization to these other allergens may allow the patient to eat the same foods with impunity.

Almost any food may produce allergy, but if one were to name a limited list of foods commonly mentioned as allergens these would include egg, wheat, milk, peas, beans, nuts, fish, onions, white potato, chocolate and some fruits.

The antigens responsible for allergic symptoms after ingestion have not been subjected to as much study as the inhalants. Allergy to cows' milk has been studied extensively. Milk is a complex liquid containing at least sixteen antigens identifiable on immunoelectrophoresis with rabbit antiserum to milk.¹ Despite some claims that heat-treated milk causes fewer symptoms than unheated milk in allergic individuals, a recent study showed that heated milk is capable of provoking symptoms in milk-allergic children.² It therefore appears that heat-resistant antigens, alpha lactalbumin, beta lactoglobulin and casein are of great interest. Goldman studied the importance of these antigens and bovine serum albumin in milk-sensitive children. He found that in milk allergy four different allergens are implicated about equally, and that the pattern varies from person to person.² Egg-sensitive individuals are usually sensitive only to the egg white, and skin reactions can usually be elicited with purified egg

albumin as well as with whole egg white. The other proteins of egg white have not been studied for antigenicity in man. Careful evaluation of individual antigens by provocative tests has not been done in other food allergies.³

The importance of the foods seems to vary with the allergic complaints. Thus fish and strawberries frequently cause urticaria, while cocoa and nuts are often involved in migraine. Urticaria frequently follows the eating of fish, shellfish, nuts or fruits. Positive skin reactions and the presence of passive transfer antibodies are more common here than in food allergy associated with other symptoms. The allergens involved have not been identified except in urticaria due to oranges, in which cholorogenic acid seems to be the allergic determinant.³

With common food, it is very difficult to detect the culprit, as any food may cause practically any manifestation. The resulting symptoms may become manifest within a few minutes to several hours after ingestion and may last many days. Furthermore, foods may contain substances, such as antibiotics, which may act as antigens. While ingestion is, of course, the usual mode of contact, it should be remembered that injections, inhalation and direct contact are also possible avenues of exposure. For instance, the miller and the housewife are exposed to inhalation of wheat, and food odors contain sufficient allergens to result in trouble. Another factor is the state of the food, as well as the quantity. A person may not have difficulty with small amounts of a food, while large amounts of the same food may result in symptoms. Some foods, according to many allergists, may be tolerated when cooked or baked although they do provoke symptoms when raw. While it is a common belief that allergic people may have allergy to foods they dislike, in the majority of cases no such allergy exists.

The diagnosis of food allergy is not accurately or even easily made by any method to date. Much confusion has resulted in recent years, especially since skin testing to foods and provocative tests from the injection of foods have frequently resulted in confusion due to too great expectation and too little supervision and cooperation. Too often other factors have been disregarded: in-

Continued

From a continuing study on nasal congestion...

timed to work while your patient does

A study being conducted by the Department of Otolaryngology, Greater Baltimore Medical Center is stockpiling evidence that points to the fast action and prolonged relief effected by Triaminic in the treatment of nasal congestion.

Begun in March 1966, the study to date has encompassed 85 patients with common nasal disorders—

and measured their response to recommended doses of Triaminic tablets.

Timed to release its oral nasal decongestant and two antihistamines within 8 hours, Triaminic was found to effect partial or complete relief in better than 82% of the subjects treated. Clearing nasal obstruction. Reducing turbinate swelling. Making breathing easier.

It's a comforting thing to know that Triaminic really works.

Triaminic[®] *timed-release tablets*

Each timed-release tablet contains:

Phenylpropanolamine hydrochloride 50mg. Pyrillamine maleate 25mg. Pheniramine maleate 25mg.

Side effects: Occasional drowsiness, blurred vision, cardiac palpitations, flushing, dizziness, nervousness or gastrointestinal upsets.

Precautions: The patient should be advised not to drive a car or operate dangerous machinery if drowsiness occurs. Use with caution in patients with hypertension, heart disease, diabetes or thyrotoxicosis.

DORSEY LABORATORIES • *a division of The Wander Company* • **LINCOLN, NEBRASKA 68501**

halants, psychic trauma, drugs, and infection. Many times the patient is given a list of skin tests and told he is "allergic" to the positive tests, not realizing that a positive skin test may or may not mean present sensitivity. Also, even though the history and provocative tests suggest food allergy, reactions to skin tests with the foods are often negative. The frequent appearance of precipitating antibodies to food antigens in the serum have not been diagnostically helpful in general. They are frequently present in individuals who are not food-sensitive.⁴ Furthermore the antigen which is absorbed from the intestine has been partially digested and may therefore be altered to a new antigenic specificity.

Although various methods for the detection of food allergy and therefore treatment have been suggested, dietary manipulation is still the most practical. It is based upon controlling the symptoms by diet and then adding foods which, if responsible, will produce clinical effects. Rotation diets, basic diets with additions, dietary methods, diets based on skin tests, and diets based on common allergic foods have been used.

Food allergies are prevalent in the United States, especially with the increased variety of foods on the market. Unfortunately, food allergy is a diagnosis frequently mentioned, occasionally studied correctly, and rarely established. It deserves more evaluation.

The Assessment of Vertigo*

A DIFFICULT problem in the assessment of vertigo from the clinician's standpoint is to get an adequate description of the patient's symptoms. People mean many different things by the term "dizziness," and patients who have nonorganic disturbances in the sense of balance seem to have much more trouble describing their symptoms than do those who have actual organic lesions such as acoustic neuroma or Meniere's disease. If a patient has true Meniere's disease, usually little difficulty is encountered in getting a description of rotary vertigo together with nausea and vomiting and the usual fluctuating loss of hearing with tinnitus in the involved ear. The caloric test or electronystagmogram may show any results from normal function to complete canal paresis. The audiologic tests are much more

valuable in making the diagnosis. In patients who have acoustic neuromas, however, the response to caloric stimulation is always reduced or possibly absent. In a large group of patients whose histories indicate episodes of true rotary vertigo, all audiologic and vestibular tests show normal results, and the neurologist is unable to find any evidence of disease of the central nervous system. In my opinion, a diagnosis of Meniere's disease should not be made in these cases until the audiologic examination reveals evidence of sensori-neural hearing loss in one ear. Much remains to be learned about the function of the vestibular apparatus and of the cochlea. The advent of a practical form of cortical audiometry may assist greatly in animal experimentation to determine the cause and the treatment of Meniere's disease and its associated conditions.

Special Management Problems in Diabetes

AS OUTLINED by Kirtley in the March* issue of MINNESOTA MEDICINE, the management of stable diabetes is relatively uncomplicated. Variations in insulin dosage usually depend on fluctuations in glycosuria, ketonuria, fasting and postprandial blood sugar levels, and the time of occurrence and frequency of hypoglycemic reactions. Such variations are by definition minimal in stable patients, and the timing of the insulin injection, meals, and exercise poses no particular problem in management.

It is the special problems posed by pregnancy, excessive lability, insulin resistance, and lipotrophic diabetes which tax the diabetologist's resourcefulness. The majority of pregnant diabetic patients have a rise in insulin requirement during the second and third trimesters of pregnancy;¹ and a rise in plasma levels of insulin occurs also in the third trimester of normal pregnancy.² This increase in insulin needs during pregnancy may be due to placental lactogen,^{3,4} in which case decreases in insulin requirement in the last trimester in diabetic pregnancy may indicate fetal death or portend neonatal complications.

In order to attain adequate control in the pregnant diabetic, the insulin dosage should be adjusted as frequently as required by variation in the different measures of the diabetic state so that the extremes of hyperglycemia with ketoacidosis and of hypoglycemia, which may be detrimental to both mother and fetus, are avoided. Rigid adherence to set doses of insulin or to a set program of insulin management may result in ketoacidosis or hypoglycemia. The need for marked reduction of insulin dosage on the day of delivery to avert catastrophic hypoglycemia has been urged¹ and should be well known. It is best to reduce the insulin dose to one fourth the usual dose or to none at all on the day of delivery. Continuous intravenous administration of glucose solution may be necessary to avoid severe hypoglycemia during the first 24 hours post partum. Insulin dosage can be subsequently gauged by determinations of glucose in the blood and urine.

Patients usually return to the pregestational needs for insulin within the first week.¹

Excessively unstable diabetes mellitus requires diligent consideration. This condition has been defined as a "syndrome of excessively variable insulin sensitivity and ketosis-proneness manifested by extreme and unexplainable short-term and long-term fluctuations in the parameters of the disease."⁵ These patients may be clinically characterized by total insulin deficiency, variable sensitivity to insulin, and excessive proneness to ketosis and leanness.⁶ Fortunately they do not comprise a large percentage of the diabetic population, but they present a most challenging problem. The best program for these patients from the standpoint of diabetic control is multiple doses of soluble crystalline insulin given before a standard feeding every six hours.^{6,7} This program lessens the swing of the pendulum of hyperglycemia-hypoglycemia. As one modifies this program of multiple doses of soluble insulin to one of varied combinations of unmodified and modified insulin in one or more doses daily, the safety zone for predictable insulin effect has been crossed. The latter fact needs particular emphasis in consideration of the proper insulin program for any patient with excessively unstable diabetes mellitus.

Bolinger and colleagues⁸ have submitted data from disappearance rates for radioiodinated insulin to support the view that unstable diabetes in some patients is best controlled by a single daily morning injection of insulin with proportionately larger amounts of soluble crystalline insulin than of the modified long-acting preparations of insulin. Williams and colleagues⁹ have also demonstrated a sustained action of regular insulin in some juvenile-onset diabetics. It may be, therefore, that patients with excessively unstable diabetes may do worse with multiple doses of modified insulin preparations. Nowhere in diabetic management is it more important to tailor the management program to the individual patient than in excessively labile diabetes mellitus.

The treatment of insulin resistance will be dictated by the cause. In acromegaly, Cush-

"All Registered Nurses are Alike"

It stands to reason. They all go through the same training; they all have to pass the same tests: they all have to measure up to the same standards. Therefore, all registered nurses are alike.

That's nonsense, of course. But it's no more nonsensical than what some people say about aspirin. Namely: since all aspirin is at least supposed to come up to certain required standards, then all aspirin tablets must be alike.

Bayer's standards are far more demanding. In fact, there are at least *nine specific differences* involving purity, potency and speed of tablet dis-

integration. These Bayer® standards result in significant product benefits including gentleness to the stomach, and product stability that enables Bayer tablets to *stay* strong and gentle until they are taken.

So next time you hear someone say that all aspirin tablets are alike, you can say, with confidence, that it just isn't so.

You might also say that all registered nurses aren't alike, either.

ing's disease, malignant neoplasia, and infections, the treatment is obvious: remove the cause and the insulin hyporesponsiveness is ameliorated. However, chronic insulin resistance with the need for 200 or more units of insulin daily with elevation of insulin antibodies in the serum is best treated with porcine insulin, especially when higher levels of antibodies to bovine than to porcine insulin can be demonstrated.¹⁰ Treatment with desalinated porcine insulin,¹¹ human insulin,¹¹ and sulfated insulin,¹² as well as treatment with adrenal steroids¹⁰ and with combinations of the oral antidiabetic agents with insulin,¹³ has also been tried with beneficial effect.

An interesting variety of insulin resistance has been described in association with acanthosis nigricans* in two patients in whom end-organ failure or cellular hyporesponsiveness was apparently involved.^{14,15}

We have recently had the opportunity of evaluating a 14-year-old girl with acanthosis nigricans, who had had diabetes for approximately one year. She had no diabetic complications. Regardless of whether she received 1,000 or more units of insulin or no insulin at all, her blood sugar levels and quantitative values for urinary glucose remained essentially unchanged. She showed no tendency to develop ketoacidosis. There was no evidence of other endocrine disease. Values for blood cortisols and urinary 17-ketosteroids and ketogenic steroids were within normal limits. Her insulin antibody levels were in the usual range for stable uncomplicated diabetes (8.7% by the Skom-Talmage method). Pharmacologic doses of adrenal steroids did not ameliorate the insulin resistance but, in fact, exacerbated the diabetes with increasing hyperglycemia. Phenformin alone and in combination with insulin had little effect. A trial with porcine insulin was not undertaken. Her condition as of the last follow-up (at 18 months) remained unchanged.

Generalizations regarding the outcome in this special group of patients with insulin-resistant diabetes secondary to cellular hypo-

responsiveness cannot be made because clinical experience with such patients has been limited to a few cases. The patient of Tucker and colleagues¹⁵ died with nephropathy and cerebellar infarction; the patient of Field and colleagues¹⁴ survived with spontaneous remission of the insulin resistance in 18 months.

Lipoatrophic diabetes is another form of insulin-resistant diabetes mellitus. It is characterized by complete absence of subcutaneous, intra-abdominal, and perinephric fat with onset usually in the teens or occasionally later, little tendency for ketoacidosis to develop, hepatosplenomegaly, hyperlipemia with cutaneous xanthomata, and marked hypermetabolism without hyperthyroidism.¹⁶ Because of the cellular hyporesponsiveness in these patients, the quantity of insulin administered apparently makes little difference; however, one should strive for optimal control with the use of insulin or a combination of oral antidiabetic agents, or both. Clinical experience with this group of diabetic patients has also been limited to a small number of cases.

Distinct from this group of patients with lipoatrophic diabetes is a larger group with lipoatrophy secondary to insulin therapy. These patients may have mildly elevated insulin antibody levels (approximately 30% binding by the Skom-Talmage method), yet insulin requirement is low (less than 40 units of insulin daily) relative to the antibody titer. We have observed that some of these patients have benefited by the use of porcine insulin; the areas of lipoatrophy have filled in, the insulin antibodies have decreased over a one-year period, but the insulin requirement has not changed appreciably.

Hence pregnancy, excessive lability, insulin resistance of whatever cause, and lipoatrophic diabetes present special management problems in diabetes mellitus and, although every program of diabetic management needs to be individualized, these special problems make tailoring of the diabetic program to the individual patient of paramount importance in treatment.

Parepectolin for quick relief of acute diarrhea
...soothes colicky pain with paregoric
...consolidates fluid stools with pectin
...adsorbs irritants with kaolin, and protects
intestinal mucosa.

Whether it's a 24-hour "bug", a food problem, or simply nervousness and anxiety, Parepectolin will bring the diarrhea under control until etiology can be determined. In some cases, Parepectolin may be all the therapy necessary.

Parepectolin®

Each fluid ounce of creamy white suspension contains:
Paregoric (equivalent)..... (1.0 dram) 3.7 ml.
Contains opium ($\frac{1}{4}$ grain) 15 mg. per fluid
ounce.
warning: may be habit forming
Pectin (2½ grains) 162 mg.
Kaolin (specially purified).... (85 grains) 5.5 Gm.
(alcohol 0.69%)
Usual Adult Dose: One or two tablespoonfuls three
times daily.

THE S.S. HOPE is a floating medical center — a fully staffed and fully equipped modern hospital which is the vehicle by which Project HOPE fulfills its mission of carrying American medical treatment and training to foreign lands where such help is not only needed but wanted. Project HOPE is a nongovernmental, nonprofit organization which is financed solely by voluntary contributions from individuals and private enterprise of North America.

THEIR HOPE — Although thousands of natives are treated on ship and ashore, the primary objective of HOPE is teaching. Every HOPE physician, nurse, or technician has his local counterpart who is trained to continue modern treatment after the ship leaves. It is a seeding process which multiplies in the underdeveloped country to improve the health of its citizens and thus their productivity and thereby creates a progressive economy and a higher living standard. The kind of economy in which communism cannot thrive!

OUR HOPE — HOPE — an acronym for Health Opportunities for People Everywhere — is a young Project only in its fourth year of operation but already the evidence is incontestable that its missions are highly successful, not only in the interchange of medical knowledge but also in promoting international friendship and goodwill.

YOUR HOPE — HOPE's basic professional staff of nurses, technicians, etc., are paid a nominal salary but most of its teaching physicians and dentists serve without financial compensation. This makes it not only our most successful foreign aid program but also our cheapest. Nevertheless, private contributions are essential. You may participate by drawing and mailing a check to:

Anatomic Lymphatic-Venous Connections Demonstrated by Lymphangiography

PRESSMAN AND BURTZ* have emphasized that it is possible for tumor cells or bacteria to pass from lymph nodes directly into the bloodstream. This fact should be taken into account in order to form an accurate concept of the role of lymphatics in the dissemination of cancer and infection.

Another lymphatic anatomic consideration that may have great bearing on the spread of cancer or infection by lymphatics is the presence of anastomoses between lymphatic vessels and adjacent veins. Lymphangiography

has dramatically demonstrated that these anatomic connections are functional. During lymphangiography, the contrast medium (Ethiodol) occasionally can be seen with image intensification fluoroscopy and spot roentgenograms to enter these direct connections from lymphatic vessels to veins. If lymphatic obstruction is present, large amounts of Ethiodol may be seen to enter veins via these communications. It seems likely, therefore, that cancer or infection which disseminates via the lymphatics may spread tumor cells or bacteria directly into the bloodstream by these lymphatic-venous anastomoses.

*Pressman, J. L., and Burtz, Mildred V.: The Anatomy of the Lymphatics: Relationship to the Dissemination of Malignancies and Infections. *Minnesota Med.* 50:789, 1967.

You May Be Right

In regard to the report on porphyria by Shuman and Snively*, I should like to mention a case in which a diagnosis of myocardial infarction was made and later proven to be porphyria.

This was a case of a farmer who developed acute chest pain while he was in a boat out fishing. The electrocardiogram was interpreted as showing a myocardial infarction. About five days following the so-called infarction he developed abdominal pain, which was considered to be a mesentery embolism. The question was whether or not he should be explored.

When I saw the patient it was my opinion that the electrocardiogram showed, instead of an infarction, pericarditis. There was probably some involvement of the muscle underlying the pericardium, but the primary change did not show the reciprocal changes that one would expect with a true infarction. Because the patient was so extremely ill, one would not say that this was an epicardial infarction. Therefore, we sought another cause for the chest pain followed by abdominal pain, and we were fortunate enough to prove the diagnosis of porphyria.

Following his recovery the patient has had very little difficulty if he stays out of the sun and away from barbiturates.

We have had several cases of porphyria with cutaneous manifestations and hepatic involvement. These can be very mild when the patient knows what to avoid, and particularly if we treat the acute episode with ACTH.

The mind's direction is more important than its progress.—Joubert

Before prescribing, see complete prescribing information in SK&F literature or *PDR*. A brief precautionary statement follows.

Contraindications: Glaucoma, prostatic hypertrophy, stenosing peptic ulcer, pyloroduodenal obstruction, or bladder neck obstruction.

Precautions: Use cautiously in the presence of hypertension, hyperthyroidism, coronary artery disease; warn vehicle or machine operators of possible drowsiness.

Usage in Pregnancy: Use cautiously, especially in the first trimester. **Note:** The iodine in isopropamide iodide may alter PBI test results and will suppress ^{131}I uptake; discontinue 'Ornade' one week before these tests.

Adverse Reactions: Drowsiness; excessive dryness of nose, throat or mouth; nervousness; insomnia. Other known possible side effects of the individual ingredients: nausea, vomiting, diarrhea, rash, dizziness, fatigue, tightness of chest, abdominal pain, irritability, tachycardia, headache, difficulty in urination. Thrombocytopenia, leukopenia and convulsions have been reported but no causal relationship has been established.

The Editor's Soliloquy

The Veto

To express an honest difference of opinion is justifiable and commendable. But some individuals are so constitutionally perverse—so contra-suggestive—so fractious—that they feel impelled to present an alternative to your every utterance; not only to every personal opinion you express, but even to every factual statement you make. They become an adversary, as it were. In their judgment you are misguided, uninformed, deluded—or even wilfully wrong. If they can't actually contradict what you say, they feel bound to at least qualify it. If not prepared to take vital issue with you, the caviller may be prone to demand finer distinctions and greater specificity in your choice of words.

If such a quibbler happens to be a neighbor and you greet him with "It looks like rain," he will veto your observation by citing a falling barometer reading. If you counter by saying that you detected a touch of mist in the air, he will cite too low a humidity reading for moisture to be noticeable.

If you comment on the exhilaration of winter, you are reminded that summer requires no snow shovelling; if you express a predilection for the balminess of summer, you are reminded that the rigors of winter kill off the bugs.

Such a person may have been your host and you thank him on your departure for a pleasant evening. He will question your sincerity and, if you glower, will speculate on your biliary function.

Should he be a colleague with whom you are discussing a case and you suggest a diagnosis of protein deficiency, he may counter with kwashiorkor; if you speculate on a middle-ear infection, you are apt to be bowled over with Guillain-Barre syndrome. What you call progeria, calcinosis, and nocturnal hemoglobinuria become in his exalted vocabulary Hutchinson-Gilford disease, Thibierge-Weissenbach syndrome, and Marchiafava-Micheli.

The contra-suggestive individual is indigenous to all areas and social classes. He has no identifying marks to alert you in advance that you are meeting up with an antagonist. Perhaps, after a futile and frustrating hour or so in his company, you decide that you will surely be invulnerable if you embark on some such irrefutable and sacrosanct subject as God, Motherhood, or Country. But you are mistaken, for he responds to the challenge with flagrant cases of atheism and heresy; illegitimacy and the unidentified orphan on the doorstep; or the enormous provocation for the Founding Fathers to turn over in their graves.

Carl O. Rice, M.D.

"I'll speak to thee in silence."—Shakespeare-Cymbeline

Old Doc Hess says: There are two kinds of "psychogenic" disorders: (1) those for which the doctor easily learns the psychic cause; and (2) those for which the doctor fails to find the organic cause.—C.O.R.

Most ignorance is vincible ignorance. We don't know because we don't want to know.—Aldous Huxley

QUESTION: A 44-year-old man has a history of a six-week visual loss in the left eye at age 25; since then he has had a three-week episode of paresthesia involving the entire right upper limb, and another ten-day episode of diplopia recently. Except for bilateral extensor plantar responses, absent abdominal reflexes, and a pale optic disc on the left side, there are no other findings. Examination of the cerebrospinal fluid shows 53 mg. protein, 10 lymphocytes, a gamma globulin concentration of 26 per cent (upper limit of 13 per cent) but no other changes. How specific for multiple sclerosis is the finding of an increased concentration of gamma globulin in the cerebrospinal fluid after protein electrophoresis?

ANSWER: The elevation of gamma globulin in the cerebrospinal fluid is not specific for any disease of the central nervous system, and this finding must be interpreted with knowledge of the entire clinical picture. Seventy per cent of patients with multiple sclerosis will have this change, and the patient described almost certainly has this disease.

But similar elevations may be encountered in neurosyphilis (e.g., tabes dorsalis), in acute viral encephalitis, in fungus meningitis, in some brain tumors, and in diseases with elevation of the serum gamma globulin. Cerebrospinal fluid gamma globulin concentration is characteristically elevated in patients with the uncommon inflammatory disease, subacute inclusion body encephalitis.

Allan J. D. Dale, M.D.
Rochester, Minnesota

QUESTION: A 50-year-old diabetic male has progressive gangrene of the toes of the right foot. In addition, there is rest pain in the foot and lower leg. Otherwise the patient shows no evidence of severe vascular disease, and the diabetes is easily controlled with insulin. A sympathectomy was performed three years ago with some symptomatic improvement. A recent femoral arteriogram reveals complete occlusion of the superficial femoral and popliteal arteries. The anterior tibial artery is patent in the mid-calf. The pain is so severe that the man wishes his leg amputated. Is there any reconstructive procedure currently available to attempt to revascularize this leg?

ANSWER: Recent technical advances in the manufacture of suture material and needles make surgery for relatively small blood vessels feasible. Femoral-anterior tibial arterial reconstruction, utilizing autogenous saphenous vein, should be considered in cases of this type. A number of patients have been relieved of pain and have been spared amputation by this reconstruction. It should be borne in mind, however, that surgery of this type is palliative and does not prevent the progression of atherosclerosis.

The Viewing Box

Cardiac Enlargement in Uremia

THE PATIENT was a 24-year-old white male with a history of chronic glomerulonephritis who received a homograph renal transplant in June, 1965. Due to a chronic rejection phase, the patient had the transplanted kidney removed in June, 1966 and has been anephric since. His course on hemodialysis has been essentially stable with good control of his uremia. In July, 1967, due to occasional anterior chest pain, a roentgenogram of the thorax was obtained and showed an enlarged cardiac silhouette (Figure 1). The patient was hospitalized for evaluation.

Two days after admission a pericardial friction rub was noted, that persisted for about 2-3 weeks. His rhythm was generally sinus, with bouts of atrial flutter. A radioisotope scan of the cardiac blood pool was done using iodine 131-labelled human serum albumin (RISA) (Figure 2).

Figure 1

Figure 2

What is your diagnosis? (See next page).

Diagnosis. Uremic pericarditis with effusion.

In Figure 2 the scan is superimposed upon the roentgenogram. It shows a small cardiac blood pool within a large cardiac silhouette, indicating the presence of a massive pericardial effusion.

Pericarditis is defined as inflammation of the enveloping membranes of the heart, i.e., the visceral or parietal pericardium, or both. Pericarditis may be the sole cardiac lesion but is more commonly seen in association with myocarditis, endocarditis, or both.

Pericarditis seems to be a relatively common complication of uremia. Before the era of dialysis, its presence was regarded as a sign of impending death. With renal transplantation and dialysis being more widely used, the following have become apparent:

- (1) Uremic pericarditis is more common than previously realized.
- (2) Uremic pericarditis may have no correlation with the clinical state of uremia.
- (3) With treatment, reports of cardiac tamponade, which was considered rare in uremia, are increasing, many with complete recovery.

The basic mechanism of the development of pericarditis in uremia is not well understood. Therapy seems to be the diligent treatment of the underlying uremia. Clinically the prognosis is less grim, and tamponade, should it occur, should be vigorously treated. Radioactive isotope scanning is a good method to confirm the presence of a pericardial effusion.

Neil Hoffman, M.D.
Department of Medicine
Hennepin County General Hospital

A Frontier Post Mortem

The Tombstone Epitaph of those days contained stories which showed why the doctor had every opportunity to become a proficient surgeon. On July 8, 1882, the paper told how Deputy Sherrill Phillips was killed while arresting a drunken Mexican who was flourishing his revolver in a saloon.

Phillips died in the saloon, and the Epitaph reported:

"A post mortem examination of the murdered man by Dr. Goodfellow, showed the nature of the wound to be as follows: The bullet entered the upper part of the right arm passing through the pectoral muscles in front of the armpit, entered the chest cavity between the first and second ribs; thence passing through the upper lobe of the right lung; thence through the upper left lobe of the lung, in the left side of which it lodged. Death occurred from hemorrhage into the windpipe and pleural cavities."*

*Richard Dunlop, M.D.: Doctors of the American Frontier.

Remedies For Fevers

Deer's flesh is a febrifuge. Periodical and recurrent fevers are cured, if we are to believe what the magicians tell us, by wearing the right eye of a wolf, salted, and attached as an amulet. There is one kind of fever generally known as "amphemerine;" it is to be cured, they say, by the patient taking three drops of blood from an ass's ear, and swallowing them in two semi-sextarii of water. Other adepts recommend for quartan fever, the salted liver of a cat that has been killed while the moon was on the wane, to be taken in wine just before the paroxysms come on.

Tumor Conference

A Liver Transplant^{*}

Dr. Walter L. Mersheimer:^{**}

Our topic this morning is liver transplantation and our first speaker is Dr. Joel Smith, resident in the Department of Surgery, who is going to discuss the history of liver transplants.

Hepatic Homotransplantation

Dr. Joel Smith:[†]

Spurred on by the success of Drs. Murray and Hume in their work with renal transplantation, Dr. C. Stuart Welch at the Albany Medical Center began his investigation into the technique and feasibility of hepatic homotransplantation. He performed auxiliary liver homotransplantations in dogs wherein the donor liver was placed into the pelvic region of the host, and its portal vein anastomosed to the distal portion of the now severed host inferior vena cava. Its own infra-hepatic inferior vena cava was ligated, and its supra-hepatic inferior vena caval cuff was then joined to the infra-renal inferior vena cava of the host. The arterial blood supply to the graft was supplied by the host aorta, without removing the host's own liver and without administering immunosuppressive therapies.

Results

Immediate function of the grafted liver was evident. Its output of bile via a cholecystostomy tube and its clearance of administered bromsulphalein were at a minimum on the third postoperative day and thence declined until the death of the host on the fifth or sixth postoperative day.

The hepatic graft's tolerance to anoxia was limited to thirty-three minutes.

Round cell invasion and mononuclear infiltration first appeared in the grafted liver on the fourth postoperative day.

Autolysis

At about the same time, Dr. Francis Moore and Dr. A. S. Sicular had been evaluating methods which could lessen the amount of autolysis and increase the critical tolerance to anoxia in the immediate post-mortem organ.² These

^{*}Presented at Surgical Conference, November 16, 1966, New York Medical College, Flower and Fifth Avenue Hospitals.

^{**}Professor and Chairman Department of Surgery, New York Medical College.

[†]Resident in Surgery, New York Medical College.

Continued

methods which included donor organ hypothermia were then employed in their series of orthotopic liver homotransplants wherein the host's liver was removed and replaced with a graft liver³. Many of these dogs survived twelve days, although as with Welch's procedures immunosuppressive drugs were not given.

Hepatic Outflow Block

Dr. Thomas Starzl and his group at Denver, Colorado, evaluated the role of hepatic anoxia in outflow block, the histologic changes in the grafted liver and other problems met with in hepatic transplantation.⁴

It had been noticed that early failures exhibited livers which were swollen, cyanotic and tense. Acute portal venous hypertension was evident. This condition was found to be caused by a block to hepatic outflow of blood by the sphincteric action of the well-developed smooth muscle layer present in the small hepatic veins. This hepatic outflow block had also been noticed in dogs suffering endotoxic, peptone and hemorrhagic shock. It was concluded that the grafted liver reacted to the transplantation anoxia with this throttling mechanism and now began to accumulate all the blood entering it until gastrointestinal infarction and hemorrhage began its deleterious attempt at decompressing this acute portal hypertension. Further attempts at hepatic transplantation had to consider reducing the amount of liver ischemia as well as perhaps reducing its supply of blood should outflow block become imminent. An extracorporeal hypothermic perfusion pump technique and various patterns of vascular anastomoses were developed to lessen these problems.

Immunosuppressive Agents

Immunosuppressive agents, notably azathioprine, were now administered to the transplant animals, and Starzl was able to prolong their survival significantly. Histologically, parenchymal destruction and perivascular inflammation was evident; however, the minor degrees of pyroninophilic* cellular invasion and monocytic invasion would lead one to conclude that these agents reduced the cellular mechanism of graft rejection.⁵ The role of the humoral factors in rejection of hepatic grafts thus became predominant, especially since Hans Popper reported the role of the hepatocyte as a target cell for antigen and antibody complexing with subsequent destruction of this cell. Sicular showed that gamma globulins can affix themselves to the hepatocytes, the blood vessels and the bile ducts of the liver graft. Other agents included Azaserine, actinomycin C, S-35 labelled methionine and, most recently, Anti-lymphocyte serum.

Starzl employed some of these agents and reported marked increases in the survival rates of grafted dogs.⁶ Twenty per cent of the dogs with hepatectomies and orthotopic liver transplants showed no clinical evidence of rejection and one third of this large series exhibited rejection that was reversible without increasing the amount or the frequency of azathioprine. A small number of the dogs were able to survive after the azathioprine was discontinued and some were reported alive well over twenty months after their transplant operation.

Of the seven reported attempts at human orthotopic liver transplants,⁷ five were done by Starzl in Colorado, one each was done by Moore and Demirleau. Six patients had primary hepatomas, the seventh, congenital biliary atresia. Two died during surgery; the others survived six to twenty-three days.

*See Test Your Word Score Page 1513.

The problems encountered included the use of severely injured and anoxic donor livers which, however, did not suffer from the detrimental complication of hepatic outflow block met with in the canine experiments. Although the livers were severely damaged, serial laboratory data showed this injury to be reversible.

Poor Clotting

The patient with a diseased liver enters the procedure with inherently poor clotting powers. During the actual transplant, acute and severe fibrinolysis compounds this problem.⁸ This phase of hypofibrinogenemia and hyperfibrinolysis is partially improved some hours after canine hepatectomy, suggesting that other organ systems can control this increased fibrinolysis in the anhepatic organism. It is also believed that on re-establishing the afferent and efferent blood supplies to the anoxic liver, fibrinolysins or their activators (which might be produced in the damaged graft) now gain access to the host circulation with detrimental results. Dr. Starzl tried to control this acute fibrinolysis in his patients by using epsilon amino caproic acid, fresh blood and fibrinogen. However, this intra-operative hemorrhagic phenomenon was soon followed postoperatively by a period of rebound hypercoagulability which was only intensified by the prior addition of clot-promoting agents.

Many patients had peripheral venous thromboses during the hypercoagulative, hyperfibrinogenemic phase which often became manifest later on as pulmonary emboli.

The histologic study of the orthotopically placed human homotransplant showed good preservation of liver function and architecture, minimal immunocyte invasion and minimal hepatocyte loss. Death was not due to liver failure or immunologic rejection. Indeed the longest survivor died of bile peritonitis secondary to a technically caused necrosis of the common bile duct.

Physiologically Favored Homotransplant

The employment of the auxiliary liver homotransplant seems advantageous in patients with medically irreversible hepatic failure wherein their own liver need not be removed at that time, if at all. Experimentally, however, it was found that in dogs having this technique and treatment with azathioprine, the grafted livers began to shrink after two weeks and continued to do so. If we recall Dr. Welch's scheme, we see that the major blood supply to the graft was furnished by the recipient's inferior vena cava. Marchioro working in Starzl's laboratory concluded that the physiologically favored liver in this auxiliary technique would be the one receiving the substrates included in the non-hepatic splanchnic venous blood flow.⁹ Should neither directly receive this important flow, the liver obtaining the greater blood flow would be the favored one. A patient's diseased liver has lost most of its capacity for this competition, and indeed this substrate dependency is lost. To facilitate a better flow of blood into the auxiliary liver graft, Starzl performed a portocaval shunt in two patients with Laennec's cirrhosis prior to the actual transplantation.¹⁰ The auxiliary livers functioned immediately but deteriorated after seven to 10 days. Nevertheless, the patients survived: one died on the 22nd day of staphylococcal pneumonia, the other on the 34th day of hemorrhagic monilial enterocolitis, cytomegalic virus inclusion disease and pneumocystis carinii infection. Active rejection of the homograft was severe only in the patient dying of pneumonia.

Continued

A third attempt at auxiliary hepatic homotransplantation was made in a 15-month-old child with biliary atresia with immediately poor results due to technical complications. Other auxiliary transplants have already been performed by Absolon, Hermann, Cree, Hume and Gliedman, the latter four not as yet reported.

TABLE
HISTORICAL EVENTS IN LIVER TRANSPLANTATION

February, 1956	First auxiliary liver homotransplants in dogs by Goodrich et al. at Albany Medical Center.
March, 1963	First clinical liver homotransplantation and first orthotopic canine liver homotransplants by Starzl et al. at Denver, Colorado.
September, 1963	Clinical orthotopic liver transplant by Moore in Boston.
January, 1964	Clinical orthotopic liver transplant by Demirleau in Paris.
November, 1964	First clinical auxiliary liver homotransplant by Absolon in Minneapolis.
February, 1965	Further clinical auxiliary liver homotransplantations by Starzl et al. in Denver, Colorado.

Case Report

Dr. Michael Antonelli:*

A 17-year-old negro male was admitted to Metropolitan Hospital on October 21, 1966, with the chief complaint of jaundice. Four days prior to admission he noted anorexia, nausea and dark urine. He later developed jaundice, experienced malaise, and had one episode of vomiting. He had not had a bowel movement for two days. There was no abdominal pain. No previous history of jaundice, dark urine or food intolerance could be obtained. He admitted to having taken two injections of heroin six weeks previously, but was not a habitual user of drugs. Past history included an umbilical herniorrhaphy in 1957. He had had pneumonia, "glandular fever", and tonsillitis as a child.

Physical Findings

Physical examination revealed a well developed, well nourished negro male in no distress: blood pressure 120/56, pulse 60, and temperature 100° F. The only positive physical findings were icterus of sclerae and mucous membranes, a grade I/VI systolic murmur at the left sternal border in the recumbent position, a liver that was barely palpable below the right costal margin, and punch tenderness over the liver. Flat plate of abdomen and chest films were negative.

Laboratory Studies

Laboratory data on admission included a bilirubin of 7.7, alkaline phosphatase of 29.5 K.A. units, albumin of 4.7, and globulin of 3.1. Sick cell prep. was negative. Hb. was 14.7 Gm., Ht. 46%, wbc. 8,500 with 25% segs., 73% lymphs and 2% eos.; platelets were 170,000, FBS 110, BUN 16 and prothrombin time 23 secs. with a control of 14.5 secs. Electrolytes were normal.

On October 24 his bilirubin was 1.8 direct—13.6 total, SGOT over 216, SGPT over 180. The patient appeared well until the night of October 24 and the morning of October 25, at which time he became markedly agitated. Physical examination showed pupils that were equal and responded to light, normal deep tendon reflexes, no pathological reflexes, and no asterixis. The liver was not palpable and by percussion appeared smaller than previously noted. He was started on Decadron, 10 mgm. I.V. Stat. and every six hours, 10% D/W, neomycin by mouth and neomycin enemas. A blood ammonia was drawn and later reported as 162 µg. %. Later in the day his coma deepened, the patient responding to painful stimuli only. His Decadron was increased to 20 mgm. every six hours intravenously.

Progress

On October 26 he was comatose, not responding to painful stimuli. His temperature had risen to 101° and râles were heard over the lung fields. His bilirubin was 7.8 direct, 20.9 total, BUN 5, prothrombin time of over 60 seconds, alkaline phosphatase of 40.3 KA units and a thymol turbidity of 11.3. A tracheostomy was performed and penicillin started intravenously. Some dark blood was obtained through a nasogastric tube and hematuria was noted.

*Resident in Medicine, New York Medical College.

At this time an exchange transfusion of 10 units of blood removed and 11 units infused was performed in 500 cc. aliquots. After transfusion his bilirubin had fallen to 16.3, his alk. phosphatase to 34 and his prothrombin time to 34 secs. with control of 14 secs. The bleeding from the tracheostomy, bladder and stomach ceased, and he was now responsive to painful stimuli with occasional spontaneous movement.

The next day, October 27, his coma was deeper again with dilated pupils. He had a respiratory and cardiac arrest while being suctioned, but regular sinus rhythm was restored within 1-2 minutes, with a blood pressure of 94/60. He required a Bird respirator for maintenance of respiration, and blood pressure had to be maintained with Isuprel and later Aramine. His blood ammonia had risen to 470 μ g.

A second exchange transfusion was performed with 13 units of fresh heparinized blood. After seven units his ammonia had fallen to 320 μ g. However, at the end of the exchange, his coma had not appreciably lightened. His body temperature fell to 94° and he was maintained on a thermal blanket, Bird respirator and vasopressors. Late that night an operation was performed.

Exchange Transfusions

Dr. William Rosenthal:*

Within the past 15 or 18 years, considerable information has been presented on the clinical course and biochemical background of hepatic coma, the complete pathogenesis of which still remains to be elucidated. On a purely empirical basis, a number of lines of therapy have been developed. Patients with hepatic encephalopathy seem to fall into two groups: those with exogenous coma and those with endogenous coma.

Exogenous Coma

In the first group the patients have something in their recent past which is responsible for the coma. Either they had some ammoniacal material such as protein, urea, etc., or they have had a drug which affects ammonia metabolism or cerebral metabolism. With removal of these materials from the diet or the therapeutic regimen, the patient usually improves.

Endogenous Coma

The second group has proven much more difficult. This includes patients with massive liver injury as seen in carbontetrachloride poisoning, acute fulminating viral hepatitis, or progressive broad deterioration of liver function as seen in the end stage of cirrhosis. In these patients the blood ammonia levels have been less well correlated with the degree of coma. Removal of potential toxic substances from their therapeutic or dietary regimen does not seem to help. It is this group in which medical results have been extremely poor to which we are addressing ourselves today. Corticosteroids have been used with some degree of success in fulminating viral hepatitis. Massive doses of corticosteroids in the hands of Katz et al.¹¹ resulted in a fall of the mortality rate from approximately 99% to around 60%. This drug has become the mainstay of medical therapy. Despite the fact that these results have been difficult to duplicate in large series, we have seen a few patients at this institution who appear to have responded to this therapy. In general, however, results have been extremely poor. Certainly the elimination of bacteria from the G.I. tract to reduce the absorption of toxins in this group has been useless. The use of dialysis will be discussed by Dr. Treser. However, in view of the failure of these efforts, a new approach has been replacement of the patient's blood with normal blood to remove the cause of the

*Associate Professor of Medicine, New York Medical College.

Continued

coma and result in improved cerebral function. Exchange transfusion¹² should be viewed as a method of "buying" time for the patient while his liver regenerates enough for survival.

Exchange Transfusion

A larger report by Trey et al.¹³ was that on seven patients from South Africa, five of whom survived as a direct result of exchange transfusion. In fact one of the patients received seven exchange transfusions and survived. Most of the patients required only one or two transfusions and the very encouraging part of this report was that each patient made dramatic response to the exchange, actually becoming far more responsive immediately after exchange transfusion. As you will recall, in our patient this did not occur. There was only a slight response to the first exchange and little or no clinical change with the second. Although these cases from the literature seem promising, some weeks later in the correspondence columns of the *NEW ENGLAND JOURNAL* the editors mentioned that one of the authors had received 11 letters from people around the world stating that they had tried exchange transfusion with failure.

Dialysis

Dr. Gerhard Treser:*

Dialysis seems to be of limited value in the treatment of hepatic coma. Many say it is of no value at all. However, we are able at least to remove ammonia at quite a fast rate and correct the pH and electrolytes. There are reports where dialysis at least achieved a temporary improvement in these patients, and we were able to reduce the ammonia from 1,000 μ gm. to 150 μ gm., with the electrolytes normal after dialysis. Our aim in this is to give the surgeon more time to prepare for the operation and to look for a suitable liver.

Dr. Mersheimer:

Thank you, Dr. Treser. I think that in introducing the next speaker I would like to state that Dr. Ian Campbell Cree joined our staff here July 1 of this year. He was trained primarily in England; then he spent a year on a Rockefeller Fellowship at the Mayo Clinic where he did exclusive research on organ and tissue transplant problems. I met him as he was completing this fellowship and tried to get him to join our staff. However, since he was here on an exchange visa, he had to leave the country for two years and went to the University of Saskatchewan where he was in the Department of Surgery and headed up their renal and liver transplant investigations.

A Liver Transplant

Dr. Ian Cree:**

Thank you, Dr. Mersheimer. It is a great honor for me to be able to work in this college. I have been tremendously impressed by the staff here and by the outstanding potential of this college. This liver transplant was in essence a last ditch attempt to save this young boy who was only 17 years of age

*Research Associate, Department of Medicine, New York Medical College.

**Associate Professor of Surgery, New York Medical College.

Continued

and who was already, as you have heard, in extremely deep coma. We did not know at the time to what extent his brain had suffered from the cardiac arrest before his surgery, and we decided therefore to give him the benefit of the doubt and attempt a liver transplant which either might of itself be permanently successful in functioning as a homograft or might, if rejected, enable his own liver to have sufficient time for recovery. Another unknown factor was the question of to what extent he still had circulating viremia or antibodies to the virus. If he still had circulating viremia without antibody formation then possibly the graft itself might be destroyed. We therefore searched for a suitable donor organ. The liver which we obtained was from the O group, which is regarded by Starzl's work as a universal donor and was therefore suitable for this patient. The liver was obtained after death of the donor by first opening the abdomen, by cannulating the portal vein and perfusing it with Ringer-lactate solution at 4°C. Fortunately, the liver showed evidence of adequate perfusion and had not suffered intra-hepatic thrombosis.

The organ was dissected out, taking with it the hepatic artery, the common bile duct, the portal vein and the inferior vena cava above and below the liver. That portion of the vena cava above the liver was divided close to the heart, and a rim of the diaphragm was removed with it. Several small veins on the posterior surface of the liver associated with the adrenal gland were divided and subsequently ligated. The organ was then placed in a dish, covered with ice-cold Ringer-lactate solution and transported to Metropolitan Hospital. There the recipient was opened and the inferior vena cava and the internal iliac artery were prepared. The first anastomosis was between the internal iliac artery of the recipient and the hepatic artery of the donor. The second anastomosis was between the vena cava of the recipient below the renal arteries and the suprahepatic donor vena cava, an end-to-side anastomosis. The inferior vena cava of the donor liver below that liver was tied off and the portal vein anastomosed in this instance to the inferior mesenteric vein of the recipient in order that the portal vein would be perfused with splanchnic blood and thus avoid the problem of liver shrinkage which has been discussed by Dr. Smith in the introduction. The final anastomosis was between the common bile duct and the upper jejunum. This particular donor liver was from an elderly lady who had gallstones. We therefore deemed it unwise to use the gallbladder for a cholecystenterostomy, as this might result in subsequent infection. We therefore did a cholecystectomy on the donor organ after it had been hooked up in the recipient—a donor cholecystectomy.

Dr. Mersheimer:

Thank you very much Dr. Cree. I want you to know that this remarkable piece of surgery was done by Dr. Cree and the surgical team at the Met. They completed this in something like six hours, which I think is fantastic.

The Coagulation Problem

Dr. Robert Goldstein:*

The problems in hemostasis which may arise in a patient such as the one we are discussing who undergoes a liver transplant can perhaps best be considered in three phases.

*Professor of Medicine, New York Medical College.

Preoperative Period

In the preoperative period, a coagulation defect may be present secondary to hepatocellular disease. Certain coagulation factors are produced in the liver: the vitamin K dependent factors (prothrombin, Factor VII, Factor IX and Factor X), Factor V, fibrinogen and probably Factor XI. The plasma levels of these factors are depressed in hepatocellular disease to a variable extent and roughly in proportion to the severity of the liver disease. This patient exhibited a marked decrease in the plasma levels of prothrombin, Factors V, VII, IX and X, but only a slight depression of fibrinogen. Factor XI was not determined. Thrombocytopenia may also be encountered in liver disease, particularly in the presence of congestive splenomegaly. The platelet count was within the normal range in this patient. The exchange transfusions temporarily improved coagulation by increasing the plasma levels of the deficient clotting factors. The exact rise in these factors was difficult to determine since heparinized blood was used for the transfusions and heparin interferes in our assay systems. It should be pointed out that any improvement obtained is of short duration since the half-life of the clotting factors involved, except for fibrinogen, has been reported to range from two to twelve hours. The patient's platelet count remained normal following the exchange transfusions as would be expected since fresh blood rather than bank blood was used. Had bank blood been used, thrombocytopenia undoubtedly would have been induced, for the platelets in bank blood are not viable *in vivo* and platelet production would not have kept pace with platelet removal. Although the fibrinolytic activity of the patient's blood was normal as determined by whole blood clot lysis and euglobulin lysis times, the second or operative phase might well have been complicated by an activation of the fibrinolytic mechanism. Stress has been shown to increase blood fibrinolytic activity in normal individuals presumably by the release of activators of the fibrinolytic mechanism. This response to stress in a patient with hepatocellular disease has been shown to be greater and of longer duration.

The Operative Period

Operative procedures in such patients may induce a severe fibrinolytic syndrome. The role of the liver in the control of *in-vivo* fibrinolysis is not clear. In our patient, although there was significant shortening of the euglobulin lysis time during the early phase of surgery indicating increased fibrinolytic activity, there was no progression to an overt fibrinolytic state, and the euglobulin lysis times returned to normal. Another complication of the operative phase might be the release of some factor from the donor liver which has an adverse effect on hemostasis. Dr. Cree has shown in animals that implantation of a liver stored for several hours at 5°C. would induce a hemorrhagic diathesis which could be partially eliminated by perfusion of the liver prior to transplantation. We found no evidence to indicate that in this case the transplanted liver induced any further deterioration of hemostasis. However, neither was there evidence that the transplanted liver improved the coagulation deficiencies.

Postoperative Period

We had little opportunity in this patient to study the third or postoperative phase. As Dr. Smith mentioned, in humans who have survived liver trans-

Continued

plantation for more than a few days, death was caused by or associated with intravascular coagulation, which may prove to be a very important problem in liver transplantation when it is possible to control graft rejection. At present, the cause of the intravascular coagulation remains obscure. From experimental data it appears that the liver normally plays a very important role in the maintenance of the fluidity of the blood by removing activated coagulation factors formed during the course of coagulation, which are necessary intermediaries for coagulation to progress to the point of completion or fibrin deposition. Evidence indicates that this is a function of the reticuloendothelial system of the liver. It could be postulated that if this function of the liver's R.E. system is impaired, the balance *in vivo* between the tendency for the blood to clot versus the inhibitory mechanisms would be shifted towards coagulation, and intravascular coagulation would occur with the production of thromboembolic phenomena and/or defibrination. Although we did a number of coagulation studies during the short postoperative period this patient survived, it was difficult for us to interpret them because of treatment the patient was receiving which included exchange transfusion with heparinized blood and hemodialysis with the use of heparin and protamine. It was evident, however, that the donor liver did not increase the plasma levels of the clotting factors which had been depressed because of liver failure.

The Postoperative Course

Dr. Smith:

On October 28, at 10:00 a.m., the patient was returned from the recovery room unconscious, receiving respiratory aid by means of a Bird respirator.

The Blood Pressure

The blood pressure remained at 70-80 systolic, and a urine output of 5 ml./hr. was raised to 16 ml./hr. with Mannitol. Ammonia levels remained at the 300-400 $\mu\text{gm}\%$ range. His hypovolemia was corrected with whole blood, packed cells and albumin. However, urinary output and central venous pressure remained low. During the afternoon, the ammonia level fell from 585 $\mu\text{gm}\%$ to 295 $\mu\text{gm}\%$, a preoperative bilirubin of 16 mg./100 ml. dropped remarkably to 7 mg./100 ml., and a preoperative prothrombin time of 45 seconds was halved. The blood pressure was maintained quite well with a titrated Aramine drip (200 mg./ltr.).

Pneumothorax

At 7:00 p.m. it was discovered that the patient had a bilateral pneumothorax. Chest tubes were inserted and connected to suction bottles. X-rays then revealed almost complete re-expansion of both lungs. Soon thereafter, the blood ammonia levels began to increase, oligurea continued, and electrolytes and urea levels remained at normal level.

On the morning of Saturday, October 29, a bilateral pneumothorax was again evident and larger caliber chest tubes were then employed. The bilirubin rose from 7 to 8 mg./100 ml., but the morning blood ammonia level was 1000 $\mu\text{gm}\%$. An abdominal sump drain recovered fluid having a high amylase content.

Hemodialysis

Hemodialysis using the left radial artery and left antecubital cephalic vein

was carried out by Dr. Treser for eight hours, and exchange transfusions were performed by Dr. Rothenburg. Additional blood was administered. Ammonia levels dropped dramatically to the 100-200 $\mu\text{gm}\%$ level, although the patient's clinical status remained unchanged. Abdominocentesis recovered 800 cc. of dark blood, and dark blood was obtained from the stomach.

During the night of October 29 the blood ammonia level was 152 $\mu\text{gm}\%$. Cedilanid was added to the regimen to combat a rising venous pressure of 11 cm. sodium chloride. The central venous pressure continued to rise to a peak level of 21 cm. sodium chloride. The ammonia level continued to remain low. Cardiac arrest occurred at 6:30 a.m. on the morning of October 30, 46 hours after the transplant.

Autopsy Findings

Dr. Alfredo La Porta:*

At autopsy, the arterial and venous anastomoses and cholechojejunostomy showed no evidence of dehiscence or leakage.

Recipient's Liver

The recipient's liver weighed 750 Gm. It was firm and a dark reddish-brown. The cut surfaces were mottled, without any distinct pattern, dark brown and congested in appearance. Microscopically there was massive destruction of hepatic cells, but with preservation of the supporting architectural framework. The preserved sinusoids were congested and the bile ducts unaffected.

Continued

scopically there was widening of the sinusoids with minimal to moderate centrilobular congestion. The hepatocytes showed now and then minimal hydropic changes and granularity of the cytoplasm. Both lungs were diffusely consolidated by bronchopneumonic process of confluent type. Liquid and clotted blood had accumulated in the bronchial tree.

The kidneys were swollen with indistinct cortico-medullary junction. Microscopically the cortices showed diffuse ischemic necrosis and good preservation of the medullae. Hemorrhagic phenomena were observed in the heart, mucosa of the gastrointestinal tract, pancreas, and urinary bladder. A hemorrhagic suffusion was found in the mesentery and the retroperitoneal soft tissue, extending along dissecting planes into the mediastinal structures.

Fig. 3—Human liver transplant. Histological section of donor liver removed at autopsy. Note the minimal changes in the hepatocytes with good preservation of the hepatic architecture. (H. & E. $\times 440$)

Dr. Levine:

I am impressed with something which has come into evidence in the school and in the center here, and that is a full-scale type of cooperative effort involving many departments and many people working as a team. Now that Dr. Cree is here and there has been development in various areas in the Department of Medicine, with interest in coagulation, transfusions, hematological aspects, and renal aspects, I hope that the challenge of organ transplantation ushers in an era of extensive clinical effort involving the cooperative teams necessary for this kind of work.

Dr. Mersheimer:

Thank you very much, Dr. Levine.

Dr. Feit, our student who stayed up all night and took these pictures, has also been helping to project them; and I think that he deserves a good hand from all of us. I too would like to add to what Dr. Levine said because this could not have been possible without the complete cooperation of Dr. Rubin, Dr. Goldstein, Dr. Rosenthal and Dr. Treser and other supporting members

of the Department of Medicine. We certainly have appreciated everything that they have done, and we hope that this will continue to be a cooperative effort. If there are any questions from the audience, we can answer them; then we will ask Dr. Cree to close. Any question from the audience?

Question:

(Dr. Burman) I would like to know why in the case of these problems exchange transfusion does not work? Theoretically it should work.

Answer:

(Dr. Rosenthal) For one thing, working has several different connotations. Does working mean that the patient wakes up for 24 hours, or just improves his level of consciousness on a transient basis, or actually walks out of the hospital? Those are the possibilities. In the cases from South Africa, all patients responded; but two subsequently died. Our patient had a brief response to the first transfusion. One of the thoughts which occurred to us was that he might have suffered so much brain damage as a result of anoxia due to the cardiac arrest that he could not respond. Another factor to be considered is that during prolonged deep coma, cerebral metabolism may be so altered that permanent damage may occur. It is well known that brain oxygen and glucose uptake are markedly reduced during hepatic coma. A brain which is not utilizing oxygen or glucose may very well go on to irreversible damage.

Dr. Mersheimer:

We have thanked the Department of Medicine, but we can never forget that the Department of Anesthesia stayed with this patient throughout. Dr. Bizzarri, are there any comments you would like to make?

Irreversible Cerebral Damage

Dr. Dante Bizzarri:*

On October 27, 1966 (the day before surgery), the patient suffered a period of cardiac arrest which, though short in duration (30-60 seconds), caused irreversible cerebral damage as evidenced by persistent apnea. There is some doubt in my mind as to the precipitating cause of the arrest, but I suspect that it followed a prolonged period of suctioning thru the tracheotomy tube.

Decerebrate Rigidity

We began, then, with an apneic patient in deep coma and decerebrate rigidity. Although there was no need for anesthetics, twice during the operation a muscle relaxant had to be administered for abdominal relaxation. Because the patient had a temperature of 90°F. esophageal, he was placed on a thermo-blanket with the intent of warming him, but despite this, his temperature declined to 88°F. Throughout the operation the heart rate remained regular (70-90) and the electrocardiogram showed no abnormalities. The blood pressure (intraarterial) ranged between 100/80-70/60 mmHg. and at times had to be supported by small amounts of vasoconstrictors. The

*Assistant Clinical Professor of Anesthesiology, New York Medical College.

Continued

blood loss of 3000 cc. as calculated by continuous perdometer measurements was replaced by continuous transfusion. The central venous pressure ranged between 6-10 cm. of water.

By 5:00 a.m., the urinary output was 250 cc., but only 15 cc. were secreted from then to the end of the operation.

The main problem was the maintenance of adequate ventilation and oxygenation in the presence of a markedly reduced lung compliance. We were forced to use high positive pressure.

Four arterial blood samples were analyzed for pH, pCO₂, and pO₂.

Blood Gas Studies:

Time	3:31 a.m.	5:00 a.m.	6:00 a.m.	9:00 a.m.
pH	7.42	7.42	7.51	7.48
pO ₂	170mmHg.	200mmHg.	160mmHg.	210mmHg.
pCO ₂	40mmHg.	47mmHg.	42mmHg.	50mmHg.

The relatively low pO₂, despite the administration of 100% oxygen delivered at higher than normal tidal and minute volumes, was a clear indication of severe pulmonary disease.

Dr. Mersheimer:

Thank you, Dr. Bizzarri. Others that I want to thank are Miss Thieler and her group of O.R. nurses who got up in the middle of the night and stayed with Dr. Cree until the end. Dr. Cree, would you care to make any concluding remarks?

Dr. Cree:

I would like to thank Dr. Bizzarri particularly for all his work. His work and success in getting this patient off the table was absolutely indispensable. The administration of the curare, I think, was a particularly courageous step fraught with danger, but it was absolutely vital in carrying out this transplant and in getting the abdomen closed. The entire work of the Anesthesia Department in helping us during the postoperative period was an indispensable part of the care of this patient. I would also like to thank all the residents, both medical and surgical, whose efforts were superhuman in looking after this patient continuously over a period of well over 48 hours. The co-operative efforts of everyone were magnificent and played no small part in getting this patient as far as he did get. That we were not successful in prolonging his survival at least for a period of weeks, I think in the last analysis was almost certainly associated with the cerebral damage which he had already received. Whether this was due to anoxia or whether the high levels of ammonia which he sustained would produce irreversible brain damage, we do not know, and I think that only future trials of this type of work in cases of transplantation will provide the answers. We learned a tremendous amount as regards the techniques and coagulation problems involved, for which we are very grateful to Dr. Goldstein and Dr. Galanakis. We also learned a great deal about the administrative problems and those of ward care and the sort of rooms and equipment required. I think that we will almost certainly be able to overcome the early problems of liver trans-

plantation in these patients. The late problems, as far as we know at this time, are identical with those in kidney transplants, namely, problems of infection, especially bizarre infections by monilia, pneumocystis carinii and so forth, and the problem of rejection when insufficient immunosuppressive drugs are administered. It is this delicate path of steering between rejection and infection which is the challenge of the postoperative care of all patients with organ transplants.

There is all the difference in the world between a man who knocks you down and a man who leaves you alone.

**Resolution Adopted by the Board of Directors
of the American Cancer Society, May 5, 1967**

Whereas, scientific evidence has established cigarette smoking as the major known cause of cancer deaths; and

Whereas, it has been estimated by the Surgeon General of the United States that as many as 300,000 excess deaths may be attributable to the effects of cigarette smoking; and

Whereas, cigarette smoking has been causally related to several million extra cases of serious illness and disability annually in the United States; and

Whereas, medical and public health institutions and personnel have a special responsibility to discourage practices that are harmful to health; and

Whereas, physicians have notably reduced their cigarette smoking (ten years ago 60% smoked cigarettes; today, less than 30%):

Now, Therefore, Be It Resolved that the American Cancer Society urge:

1. That physicians, dentists, nurses and other medical personnel do everything possible to reduce further cigarette smoking both by example and by advice concerning the health hazards of smoking, and
2. That the sale of cigarettes by medical and health institutions be discontinued, and
3. That hospitals, clinics, health centers and physicians' and dentists' offices discourage smoking by personnel and patients through appropriate restrictions and signs.

Come What Might, I Would Be a Doctor of Medicine

It may seem strange that I remember him, for he died in '83 when I was not quite ten years old. But, although not talkative, (my father) had a powerful and attractive personality. This brought him tremendous popularity and a large clientele. He was what doctors were in those days—both physician and surgeon, but it was his great skill in surgery that filled his offices.

When Garfield was shot, he was called in—quite too late. It has always been my belief that had he and Agnew been given a free hand, the pitiful death of one martyred President might have been avoided. However, this is merely the faith of a devoted son that speaks.

Those offices of his had an irresistible fascination for me. Father said I was too serious for a child, because I sought my companions among older people. I must have been an odd little figure, flitting in and out of those crowded waiting-rooms and talking with any whom I could engage in conversation. . . . In fact, he used to take me with him in his sleigh in winter to the Children's Hospital; and he even took me to see his patients when he made his rounds to their homes.

His death at only forty-one years of age was a fearful shock. At my grandmother's, where I had been taken in order to leave our home as quiet as possible, they woke me up in the night—I had been dreaming that he was dying—and told me. It had never entered my head that so strong, wise, and beloved a man could die.

His death did two things to me: first, I definitely decided that prayers were not answered and that Dr. Sunderland, our pastor, was wrong in supposing that God was merciful; and second, I resolved that, come what might, I would be a Doctor of Medicine.*

*Bailey Ashford (1873-) in *Why We Became Doctors*, edited by Noah Fabricant, 1954.

A large, dark, grainy microscopic image showing numerous spermatozoa with long, wavy tails. In the upper left corner, there is a smaller, square inset showing a different view of spermatozoa, which appear more clustered and less motile.

New view of an oral contraceptive at work

Although suppression of ovulation remains the primary mode of action of oral contraceptives, newer knowledge indicates that products like Norinyl-1— a combination of both low-dosage progestogen and estrogen for the full treatment cycle— may provide multiple action that helps explain their unexcelled record of contraceptive effectiveness. This report explores the possible secondary protective mechanisms offered by combined hormonal administration.

Accumulating evidence has indicated that sparse, highly viscous cervical mucus has a possible adverse effect on the motility and survival of spermatozoa.

The estrogen-opposing progestational ingredient of Norinyl-1 (norethindrone 1 mg. with mestranol 0.05 mg.) changes the usual mid-cycle picture of a thin, watery cervical mucus. The result—a built-in barrier that appears to inhibit sperm from reaching the ovum should one be released. The inset in the adjoining photograph shows immobile spermatozoa as they appear in cervical mucus taken from a patient treated with Norinyl-1.

How the estrogen-opposing action of Norinyl-1 creates cervical mucus that may be hostile to sperm penetration

Normally, estrogen activity during the fertile midcycle stimulates the production of a profuse and watery cervical mucus that permits maximum sperm motility and promotes penetration.

But what happens when Norinyl-1 is administered? Its potent progestogen, norethindrone, opposes estrogen stimulation of cervical mucus. Consequently, the amount of mucus decreases and its viscosity increases. This results in a sparse but thick mucus barrier that appears to diminish the vitality of the sperm and to impair its powers of penetration.

The role of viscous cervical mucus as a secondary action of Norinyl-1

In a report on 89 patients taking this medication,* cervical mucus obtained from cycle day 5 to cycle day 29 appeared scant and thick and exhibited little or no Spinnbarkeit.

In the opinion of this investigator, the effect on cervical mucus may be sufficient to prevent conception.

*Cohen, M. R.: Symposium: Mechanisms of Action of Low Dosage Oral Contraceptive, Yale University Medical Center, New Haven, Conn., April 6, 1967.

Normal cervical mucus at midcycle in untreated patient is known to permit sperm motility... promote sperm penetration.

Cervical mucus is thin and watery with a stretchability (Spinnbarkeit) of 15 to 20 cm.

Thin, watery mucus crystallizes into this well-defined, fernlike pattern within a minute.

Spermatozoa appear healthy, are active and freemoving.

Viscous cervical mucus at midcycle produced by Norinyl-1 appears to impair sperm vitality... inhibit penetration.

Cervical mucus is scanty, thick and viscous. Spinnbarkeit is 1 cm. or less.

In thick, viscous cervical mucus the fern pattern is poorly defined or absent.

Immobile spermatozoa as they appear in cervical mucus taken from a patient treated with Norinyl-1.

How Norinyl-1 alters normal endometrial responses— another possible protective mechanism

Let us suppose that an ovum is released—as occurs in an occasional, rare case—and somehow a sperm succeeds in penetrating the cervical mucus barrier. Should this come about, the additional action of Norinyl-1 may protect the patient from unwanted pregnancy. The theory is that progestogen intake makes endometrial tissue unreceptive to implantation.

Endometrium of
untreated patient

Normally, the endometrium progresses through a proliferative phase stimulated by estrogen and a secretory phase stimulated by progesterone. During the secretory phase the endometrium is receptive to the fertilized ovum.

Endometrium produced
by Norinyl-1

When Norinyl-1 is administered its progestogen component—norethindrone—accelerates the secretory phase and suppresses glandular and vascular development.

new Norinyl-1[®]

(norethindrone 1mg. $\bar{c}$ mestranol 0.05mg.) tablets

Reduction of oral contraceptive dosage to lowest effective levels has become a well-accepted principle of conservative medical practice. In keeping with this view, Norinyl is now available in a new strength in which both norethindrone and mestranol are reduced 50 percent. Studies show that Norinyl-1 achieves fertility control with only 1.05 mg. of combined progestogen and estrogen per tablet.

Norethindrone was first reported for use as a progestational agent in human beings in 1955. Norethindrone 2 mg. with mestranol 0.1 mg., as an oral contraceptive, is currently in use by over 2,000,000 women. Clinical experience now establishes that Norinyl-1 also amply meets the criteria of reliability and safety.*

*Symposium on Low-Dosage Oral Contraception, Palo Alto, Calif., July 15, 1965.

PRESCRIBING INFORMATION

Contraindications: 1. Patients with thrombophlebitis or with a history of thrombophlebitis or pulmonary embolism. 2. Liver dysfunction or disease. 3. Patients with known or suspected carcinoma of the breast or genital organs. 4. Undiagnosed vaginal bleeding.

Warnings: 1. Discontinue medication pending examination if there is sudden partial or complete loss of vision or if there is a sudden onset of proptosis, diplopia, or migraine. If examination reveals papilledema or retinal vascular lesions, medication should be withdrawn. 2. Since the safety of Norinyl-1 in pregnancy has not been demonstrated, it is recommended that for any patient who has missed two consecutive periods, pregnancy should be ruled out before continuing the contraceptive regimen. If the patient has not adhered to the prescribed schedule, the possibility of pregnancy should be considered at the time of the first missed period. 3. Detectable amounts of the active ingredients in oral contraceptives have been identified in the milk of mothers receiving these drugs. The significance of this dose to the infant has not been determined.

Precautions: 1. The pretreatment physical examination should include special reference to breast and pelvic organs, as well as a Papanicolaou smear. 2. Endocrine and possibly liver function tests may be affected by treatment with Norinyl-1. Therefore, if such tests are abnormal in a patient taking Norinyl-1, it is recommended that they be repeated after the drug has been withdrawn for 2 months. 3. Under the influence of estrogen-progestogen preparations, preexisting uterine fibroids may increase in size. 4. Because these agents may cause some degree of fluid retention, conditions that may be influenced by this factor, such as epilepsy, migraine, asthma, cardiac, or renal dysfunction, require careful observation. 5. Although a cause and effect relationship has not been established, Norinyl-1 should be used with caution in patients with a history of cerebrovascular accident. 6. In relation to breakthrough bleeding, as in all cases of irregular bleeding per vaginam, nonfunctional causes should be borne in mind. In cases of undiagnosed vaginal bleeding, adequate diagnostic measures are

indicated. 7. Patients with a history of psychic depression should be carefully observed and the drug discontinued if the depression recurs to a serious degree. 8. Any possible influence of prolonged Norinyl-1 therapy on pituitary, ovarian, adrenal, hepatic or uterine function awaits further study. 9. A decrease in glucose tolerance has been observed in a small percentage of patients on oral contraceptives. The mechanism of this decrease is obscure. For this reason, diabetic patients should be carefully observed while receiving Norinyl-1 therapy. 10. Because of the occasional occurrence of thrombophlebitis and pulmonary embolism in patients taking oral contraceptives, the physician should be alert to the earliest manifestations of the disease. A cause and effect relationship has not been demonstrated. 11. Because of the effects of estrogens on epiphyseal closure, Norinyl-1 should be used judiciously in young patients in whom bone growth is not complete. 12. The age of the patient constitutes no absolute limiting factor, although treatment with Norinyl-1 may mask the onset of the climacteric. 13. The pathologist should be advised of Norinyl-1 therapy when relevant specimens are submitted.

Side Effects: The following adverse reactions have been observed with varying incidence in patients receiving oral contraceptives: nausea, vomiting, gastrointestinal symptoms, breakthrough bleeding, spotting, change in menstrual flow, amenorrhea, edema, chloasma, breast changes (tenderness, enlargement and secretion), loss of scalp hair, change in weight (increase or decrease), changes in cervical erosion and cervical secretions, suppression of lactation when given immediately postpartum, cholestatic jaundice, erythema multiforme, erythema nodosum, hemorrhagic eruption, migraine, rash (allergic), itching, rise in blood pressure in susceptible individuals, mental depression.

The following occurrences have been observed in users of oral contraceptives. A cause and effect relationship has not been established: thrombophlebitis, pulmonary embolism, neuroocular lesions.

The following laboratory results may be

altered by the use of oral contraceptives: increased bromsulphalein retention and other hepatic function tests, coagulation tests (increase in prothrombin, factors VII, VIII, IX and X), thyroid function (increase in PBI and butanol extractable protein-bound iodine and decrease in T₃ values), metapyrone test, pregnane diol determination.

Other side effects reported to have occurred in association with use of this drug are dizziness, hirsutism, pains in legs, back, chest and abdomen, dysuria, drowsiness, vaginal discharge, libido increased and decreased, eruptions, hypermenorrhea, hypomenorrhea, increased appetite, G.U. infections, varicose veins, abdominal fullness, acne, headache, nervousness, allergies, blurred vision, pain in eyes, and itching in eyes. For complete clinical data, see package insert.

Dosage and Administration: 1. One tablet of Norinyl-1 is administered orally for 20 days beginning on day 5 of the menstrual cycle. (Count day 1 of the cycle as the first day of menstrual bleeding.) Repeat this dosage schedule for each cycle. 2. If no menstrual period occurs after a cycle of treatment (20 tablets) in which patient adhered to the schedule, the patient must be instructed to resume taking the Norinyl-1 tablets 7 days after the previous 20-day course was completed. For example, if the last pill of a previous cycle had been taken on a Sunday, then a new cycle of treatment should begin on the following Sunday. 3. In the postpartum woman, it is recommended that the first cycle of treatment should begin on day 5 of the first menstrual cycle. However, Norinyl-1 should not be administered during lactation.

Availability: Norinyl-1 (norethindrone 1 mg. with mestranol 0.05 mg.)—Dispensers of 20 and 60 and bottles of 250 tablets.

Medical Seminar

Syncope

Simple or Serious?

Presented as a Seminar

Sponsored by

The Faculty of the Mayo Graduate School of Medicine

SYNCOPE is that loss of consciousness due to an acute decrease of cerebral blood flow.¹ Although quite common in human experience, only when it is recurrent does the patient consult a physician. While most fainting experiences are trivial, sometimes they are indicative of a serious disorder, and rarely is the faint irreversible with sudden death ensuing. All too often the physician merely attempts to exclude a convulsive disorder and, having done so, relegates the patient's symptoms to the category of "the simple faint."²

Syncope is a symptom of a large number of disorders, having certain precipitating factors, warning signs, characteristic features during the unconscious period, and certain post-syncopal residua. The history is inadequate if the physician inquires only into the syncopal attack itself: whether or not there were convulsions, urinary or fecal incontinence, biting of the tongue, sweating, or pallor. Often overlooked are such factors as lack of food, degree of fatigue, emotional factors, position and activity of the body at the onset of syncope, environmental temperature, and any recent illnesses requiring prolonged bedrest. One must not overlook any warning symptoms such as angina, cardiac irregularities, paresthesias, vertigo, or any involuntary movements. There may have been no warning symptoms.

Usually syncope is classified according to the underlying physiological mechanism; but this

tends to be cumbersome, especially when more than one mechanism is operating.

Vasovagal Syncope

This is the classic simple faint. The warning symptoms may be abolished by atropine; yet the patient still faints.³ He is almost always in the upright position at the onset of the attack.

This form of syncope is a general response of the organism to fear or injury. Many of the physiological changes present are commonly seen with fear, but flight is not possible. Active vasodilatation in muscles occurs in preparation for flight, but there is no compensatory increase in muscular activity to aid venous return; nor does the cardiac output increase. Marked fall in blood pressure occurs as a result of the vasodilatation with sudden acute loss of arteriolar tone.⁴

Barcroft et al.⁵ have shown that at the time the blood pressure falls, there has been marked decrease in peripheral resistance, much of which can be accounted for by increased blood flow to muscle, amounting to the shunting of as much as 1500 ml. of blood per minute. Uvnas⁶ found that the vasodilatation in muscle is mediated through cholinergic sympathetic vasodilator fibers. Using the human centrifuge, Cohen and Silverman⁷ demonstrated that blackout occurs at a much lower "G" when the subject is afraid than when he is either confident

Continued

or defiant. In the former situation, he secretes predominantly epinephrine, while in the latter norepinephrine is secreted.

Orthostatic Hypotension

This differs from vasovagal syncope chiefly in that the circulatory disturbance is more chronic, so that fainting tends to occur repeatedly upon assuming the erect position.

Adaptive Mechanism

Certain adaptive mechanisms are required in man to counteract the gravitational effect upon circulating blood. Without these mechanisms, excess pooling of blood occurs in the lower extremities on standing, and the cerebral blood flow is markedly reduced. These mechanisms include:⁸

1. Peripheral vasoconstriction, which is mediated through pressor receptors in the aortic arch and carotid sinus via the vasomotor centers and sympathetic outflow.
2. Reflex tachycardia, which occurs concurrently with arteriolar constriction and aids in maintaining cardiac output.
3. Reflex augmentation of respiration and increased muscle tone, both mechanisms increasing venous return.
4. Reflex venous constriction which resists pooling of blood and forces blood from the venous reservoir into the circulation.

Reaction to Assumption of Upright Position

The normal reaction when tilted from recumbency to the erect position is an immediate drop in systolic pressure of 5 to 40 mm. Hg., but with a prompt rise, so that within 30 seconds the pressure equals or exceeds that at the recumbent level. But, as with many physiologic control systems, there is a wide variation in effectiveness even among normal persons, and some healthy individuals have poor postural adjustment. They complain of dizziness or faintness on standing, but the symptoms are generally mild or transient and usually seen in tall thin individuals with poor muscle tone or in those who have recently been subjected to prolonged bed rest.

Barker,⁹ in 1933, stated that for the diag-

nosis of orthostatic hypotension there must be an immediate, persistent, and consistent drop of at least 50 mm. Hg. systolic and a corresponding but smaller drop in diastolic pressure. Reflex tachycardia on standing is often but not always absent. Likewise, there are no symptoms of autonomic overactivity prior to the loss of consciousness.

Differential Diseases

Orthostatic hypotension was first described by Bradbury and Eggleston¹⁰ who noted its occurrence in diseases of the nervous system and emphasized the classical triad of postural hypotension with syncope, anhidrosis,* and impotence. This syndrome may be seen as part of the clinical picture in many diseases of the nervous system, both central and peripheral, and in several endocrinologic and metabolic disorders. The following is only a partial list of such diseases: craniopharyngioma, parasellar and posterior fossa tumors, multiple brain infarcts, Wernicke's encephalopathy, tabes dorsalis, syringomyelia,* porphyria, hypopituitarism, hypothyroidism, Addison's disease, and the peripheral neuropathy due to diabetes or amyloidosis. Sympathectomy or ganglionic blocking agents may be responsible. Micturition syncope seems to be merely a special type of orthostatic hypotension.

After the above disorders have been excluded, there still remain some patients in whom an underlying disease cannot be found. As one might expect, they are labeled as having idiopathic orthostatic hypotension,¹¹ which appears to be a primary degenerative disease of the nervous system beginning in the autonomic tracts. Eventually there may be progressive bilateral symmetrical involvement of the motor systems—corticospinal and corticobulbar tracts, basal ganglia, and cerebellum. This is manifested clinically by a variable picture in which Parkinsonian features, hyperreflexia, and pathologic reflexes may be seen, together with such signs of autonomic involvement as anisocoria and varying degrees of anhidrosis.

The basic disturbance in orthostatic hypotension is an autonomic dysfunction which results in impaired arteriolar constriction on standing. As can be seen from the above, the defect may occur at any level of the reflex arc

*See Test Your Word Score Page 1513.

—hypothalamus, brain stem, spinal cord, or peripheral nerve.

Luft and von Euler¹² showed decreased spontaneous excretion of norepinephrine in this condition. Hickler¹³ confirmed this and found a diminished norepinephrine response to tilt-table testing. Aldosterone excretion is reduced, probably due to lack of a stimulus for its secretion.

Cardiac Dysfunction

Cardiac arrhythmias, ischemic heart disease, congenital cardiac anomalies, and valvular disease may all give rise to syncope. The lesion may be extracardiac, influencing the heart on a reflex basis. It should be remembered that not all fainters who happen to have heart disease have their syncope on a cardiac basis. The onset of cardiac syncope is often quite abrupt, frequently without warning symptoms, and occurs independently of the position of the patient. Many patients with cardiac syncope have some convulsive movements while unconscious.

Stokes-Adams Syndrome

Stokes-Adams syndrome is the classic condition in which a cardiac arrhythmia results in syncope. The syncope is not due to the slow heart rate per se, but rather to asystole or ventricular fibrillation which occurs during the transition from partial to complete heart block. Rowe and White¹⁴ mention patients with heart block who were able to tolerate pulse rates in the twenties while ambulatory, and from five to 10 while recumbent, without experiencing syncope.

Myocardial Infarction

Loss of consciousness rarely occurs following angina pectoris in the absence of valvular disease but is fairly frequent in myocardial infarction, and here it is apt to be severe and prolonged. The loss of consciousness may be due to any one or a combination of the following factors: intense pain, arrhythmias, reflexes arising from coronary vessels, or a diminished stroke volume from a weakened myocardium. Persistence of the signs of vasomotor collapse, including pallor and sweating, in the post-syncopal period should alert the physician to the possibility of myocardial infarction, espe-

cially in the patient over 40.

Aortic Stenosis

Cowper,¹⁵ in 1706, first noted the common occurrence of syncope in patients with aortic stenosis. Hammersten¹⁶ studied 63 patients with this disease and found recurrent syncope to be present in 12. Seventy-five per cent of the patients with syncope had angina pectoris, and 94% of this group showed radiographic evidence of left ventricular enlargement. This is the classic example of "effort syncope," for in the great majority the faint occurs during or soon after exertion, and in most it is preceded by angina pectoris. Sometimes the faint can be aborted by standing still. The exact mechanism responsible for the loss of consciousness is not known. Electrocardiograms taken during the syncopal period have failed to reveal any consistent pattern. The fact that effort usually precipitates the faint and that it is often accompanied by angina suggests that there is inadequate outflow through the stenosed aortic valve, leading to both coronary and cerebral insufficiency. Peripheral resistance falls during exercise, but normally this is compensated for by augmented cardiac output, which fails to occur in aortic stenosis.

A few patients with syphilitic aortic insufficiency faint during exertion, presumably due to involvement of the coronary ostia.

Congenital Heart Disease

Patients with the cyanotic forms of congenital heart disease may faint after exertion. This is most commonly seen in children with tetralogy of Fallot.* Exercise increases the removal of oxygen in skeletal muscle, and markedly unsaturated venous blood enters the right side of the heart, a portion of this oxygen-poor blood passing through the shunt to the left ventricle and out to the body. As the blood flow through the lungs is little increased, the arterial oxygen saturation drops rapidly, and the patient loses consciousness as a result of cerebral anoxia.¹⁷

Irritable Carotid Sinus

A hyperirritable carotid sinus may lead to cardiac syncope on a reflex basis. Although the occurrence of significant cardiac slowing

Continued

*See Test Your Word Score Page 1513.

and even asystole on carotid sinus massage is fairly common, spontaneous fainting from this cause is not. In making this diagnosis one should satisfy himself that the induced faint is identical with the spontaneous faint; asystole is long enough to produce symptoms; and fainting has not been produced by massage or occlusion of the artery below the sinus. Usually there is vagal bradycardia with subsequent fall in blood pressure—the so-called “cardio-inhibitory type.” Other types have been described but are either rare or unproven. A hypersensitive carotid sinus may occur with arteriosclerosis or thrombosis of the carotid artery, neoplasms or inflammations in the neck, carotid body tumors, and digitalis toxicity. Cardiac syncope in the presence of atrial fibrillation may be due to a digitalis-potentiated stimulation of a hypersensitive carotid sinus.¹⁸

Pulmonary Disorders

Tussive syncope is the fainting which accompanies a severe bout of coughing, usually seen in middle-aged athletic men who have a history of chronic bronchitis. There appear to be two mechanisms underlying the syncope. A greatly increased intrathoracic pressure, which may reach 250-300 mm. Hg., develops during the episode, is transmitted to the cerebrospinal fluid compartment, and squeezes blood from the cranium so that the brain rapidly becomes anoxic. The increased intrathoracic pressure also results in decreased venous return to the heart with fall in cardiac output.¹⁹

Effort syncope may be found in pulmonary hypertension, either primary or secondary, its basis being a decreased cardiac output. As the right ventricle fails, there is a gradual fall in systemic pressure.

Syncope Due to CNS Disorders

Syncope is uncommon in diseases of the cerebrovascular system. When it does occur there is usually advanced occlusive disease of several of the large neck vessels. Focal neurological signs generally accompany the cerebral ischemia, and syncope is often without warning and prolonged. Syncope due to occlusive disease of the carotid artery usually does not occur un-

less the disease is bilateral or a hypersensitive carotid sinus is present.²⁰ Digital compression of the carotid artery, in order to induce syncope, should be avoided when occlusive vascular disease is suspected.

Syncope has been thought to be due in some cases to localized cerebral vasospasm. Weiss and Baker²¹ described a type of syncope in which carotid sinus stimulation causes unconsciousness within three to four seconds without alteration of blood pressure or heart rate. They felt it was due to a reflex acting on the mid-brain center regulating consciousness. Localized cerebral vasospasm has been incriminated as responsible for the syncopal attacks rarely seen in migraine, hypertensive encephalopathy, neurocirculatory collapse, and cough syncope.

Diagnosis

Neurologic Examination

Having obtained a careful history from the patient and any witnesses, and after excluding such conditions as may be confused with syncope—such as epilepsy, vertigo, hyperventilation, hysteria, and migraine—a detailed general and neurological examination must be performed in an attempt to uncover the underlying condition responsible for the recurrent syncopal attacks. Specific findings, such as postural hypotension, heart block, or advanced peripheral neuropathy, will be important clues to the nature of the spells. In the majority of patients, however, examination will show either no abnormalities or nonspecific findings that must be interpreted with prudence. A causal relationship between signs and symptoms must be established.

Laboratory Tests

Electroencephalography is generally of help only in separating epilepsy from syncope, not in the diagnosis of syncope, as here the interictal record is usually normal.²² In a study of syncope among 195 college students, Williams and Allen²³ found no correlation between incidence of electroencephalogram abnormalities and incidence of loss of consciousness. Gastaut and Fischer-Williams²⁴ found normal records in 83% of 218 patients with syncope. Ades,²⁵

however, found a much higher incidence of electroencephalogram abnormalities in pilots who had lost consciousness during flight. Had his criteria been used in selection of pilot candidates, 75% of the individuals involved would have been eliminated from flight school.

Electrocardiograms are of value only if they are unequivocally diagnostic of a cardiac disorder which may be associated with loss of consciousness.

Provocative measures such as carotid sinus massage, tilt-table testing, and hyperventilation may be carried out. Positive results can be diagnostic only when they produce symptoms identical to those in the spontaneous attacks.

One should be cognizant of the relative frequency of the causes of syncope. In 1961 Wayne categorized 510 patients with this complaint (see Table).²⁶

Conclusion

Syncope is usually a benign transitory condition. Occasionally it may indicate the presence

"George wants to know if it's okay to take his cold medicine now, Doctor, instead of seven o'clock?"

The long-continued action of Novahistine LP should help you both get a good night's sleep. Two tablets in the morning and two in the evening will usually provide round-the-clock relief by helping clear congested air passages for freer breathing. Novahistine LP also helps restore normal mucus secretion and ciliary activity—normal physiologic defenses against infection of the respiratory tract. Use cautiously in individuals with severe hypertension, diabetes mellitus, hyperthyroidism or urinary retention. Caution ambulatory patients that drowsiness may result. Each Novahistine LP tablet contains: phenylephrine hydrochloride, 25 mg., and chlorpheniramine maleate, 4 mg.

New drugs take exams, too.

Today, virtually every medical school in the United States cooperates with pharmaceutical manufacturers in the clinical evaluation of new and promising drugs. Just as you might find it significantly more difficult to practice medicine without the useful new compounds made available through original pharmaceutical research in the past twenty years—prescription-drug manufacturers would find it equally difficult to obtain extensive, long-term, dependable evaluations of new therapeutic agents without the close cooperation of medical staffs and clinical

facilities of medical schools and teaching hospitals. Such cooperation leads toward more effective care of more patients—the common goal of medical and pharmaceutical research—toward reduction in the cost of disease, toward increase in useful longevity.

This message is brought to you as a courtesy of this publication on behalf of the producers of prescription drugs.

Neurological Conference

Mental Retardation Associated with Epilepsy*

Doctor David Cannom:**

The patient is a 28-year-old, white, single woman who presently lives with her elderly mother.

Past History

She had been the product of a normal pregnancy and delivery and had remained in good health until age 5½ when she had a febrile illness accompanied by convulsions. She was taken to the hospital where she presented with hemiataxia and bilateral choked discs. Although a craniotomy was performed for a suspected brain abscess, nothing was found. Because the patient subsequently improved clinically, no further operative procedures were undertaken in spite of the fact that a postoperative air study had suggested the possibility of a right parietal mass in the area of the brain.

According to the mother, the patient's early normal mental development had been interrupted at the time of this febrile illness. At age seven, frequently recurring grand-mal seizures appeared. Ultimately, fair control of these seizures was obtained with dilantin and phenobarbital. She continued in school through the seventh grade but did very poorly academically.

Present Illness

The patient was first seen at University Hospitals in October 1957 at age 19, for further evaluation of her seizures and was followed in both Neurology and Psychiatry Clinics until March 1958. She was then having approximately 15 psychomotor seizures a month although there were extended intervals when she was seizure-free. Intelligence tests showed her to have a mental age of eight years 10 months (Stanford-Binet) and an I.Q. of 59. Psychiatric therapy was given in an attempt to control her temper tantrums which usually occurred only with her family, but this was not successful. The psychiatrist felt that she would function best doing simple work under supervision.

She was admitted to the hospital in January 1958 in an attempt to obtain

*Neurological Conference held February 23, 1967. These conferences are an integral part of the Comprehensive Clinic Program at the University of Minnesota Hospitals.

**Student Doctor, University of Minnesota Hospitals.

Continued

better control of her seizures and to definitely rule out the possibility of a space-occupying lesion. An electroencephalogram showed a marked hemispherical abnormality on the right, but a pneumoencephalogram was unremarkable. Following discharge on dilantin and mebaral, the patient was committed to the Cambridge State School and Hospital in March 1958 by her local probate court. During this period her seizures were well controlled.

Progress

In May 1964 trial placement at the St. Cloud Nursing Home was attempted, but after 10 months she was discharged home. Although trained in dietary areas within the hospital, she had worked as a nurse's aide in St. Cloud.

She was again seen at University Hospitals in June 1966, since her seizures had become more frequent. These seizures were both grand-mal and focal motor in type. An increase in anticonvulsant medication failed to significantly reduce the number of attacks. In December 1966 she fell during a seizure and sustained a fracture of the left knee. Again in March 1967 she fell during a seizure and received a laceration requiring eight stitches above her left eye. A month later she sustained a black eye after a fall.

At the present time she is having approximately one to two grand-mal seizures a week and many more transient psychomotor seizures.

A recent electroencephalogram was moderately abnormal, showing hemispherical asymmetry with slowing over the left temporal area. There were isolated spikes, runs of spikes, and spike-wave complexes predominantly to the right of the central vertex. At times more active spiking was present in the left posterior temporal area. Her present medications include dilantin 400 mg. daily, mebaral 200 mg. daily, and mysoline 500 mg. daily. Of late, she has become quite ataxic, possibly due to the dilantin.

The patient's family relationships have deteriorated in the past few months. She has had frequent fights with her mother and on one occasion threw kitchen objects at her. Her mother is afraid of her and admits to being unable to control her. The patient spends her day watching television and doing a few household chores, with essentially no interests outside the home.

Neurological Evaluation

Dr. Robert Soll:*

According to the history, her original episode was probably an infectious process or similar diffuse inflammatory involvement of the brain. An acute encephalitis of viral origin or an encephalomyelitis could produce extensive damage. After recovering from the acute illness, she had changed both in personality and intelligence. In addition she became plagued by frequent seizures. Throughout the years there has been no significant change in her general condition, and it will probably continue to remain static for the rest of her life without any hope for further improvement.

Progress

Prognostically, complete control of her seizures would be difficult to attain in view of her past history of recurrent seizures despite medication. Since there have been brief periods outside the home when she apparently has been seizure-free, reasonably good control may be possible; factors such as poor

*Neurologist, University of Minnesota Hospitals.

interpersonal relationships at home and unreliability in taking her medications could have contributed to her failure to remain seizure-free.

Treatment

In treating this patient an attempt should be made to secure stable living conditions free of anxiety. Her daily life should have regularity and some supervision, particularly for the medications. Another immediate situation which requires attention is her ataxia. In most situations, a period of hospitalization would help to resolve the question of whether drug intoxication or a progressive lesion were causing the disturbance. Since the patient's original illness was accompanied by ataxia, one might surmise that cerebellar damage was incurred at that time, thus reducing her tolerance to dilantin. In this light, amounts usually considered safe in the average adult might actually be toxic for this patient. Since she has had several falls recently, striking her head, the possibility of a chronic subdural hematoma should also be considered.

Psychological Evaluation

Miss Susan Goodman:*

The patient came readily to the test situation and was friendly, cooperative and chatty throughout. She became quite involved in the procedures and seemed concerned about performing at her best. Although she sought frequent reassurance from the examiner, she appeared to evaluate her capabilities realistically. Her pleasure at unexpected successes resembled the reaction of a child. Although her approach to problem solving was not very systematic, when her attention was directed to the right aspect of a problem, performance often was improved. In this situation she showed none of the hostility and temper described as typical of her behavior at home.

Present test results corroborate the results of tests given 10 years ago in which the patient performed at the mentally defective level. Although the present test results show no evidence of deterioration, it appears that the patient is presently functioning at the upper limit of her capacity. Information obtained from the patient's mother on the Vineland Scale of Social Maturity indicates that she would be incapable of independent self-support and would indeed have difficulty in caring for herself.

Dr. John Brantner:**

It is very interesting that both Miss Goodman and the psychologist 10 years ago noted the evenness of temper, pleasant disposition, and failure to become upset when she was frustrated with anything that she couldn't do. Yet on both occasions the problem for which she was referred was difficulty in controlling her behavior at home.

Social Service Evaluation

Mrs. Janet Johnston:†

Environmentally, the patient's family stems from a rural background. There are eight brothers and sisters, one of whom died of Hodgkin's disease. Since the father's death last year, the mother has maintained a close relationship with the married children, particularly one of the daughters. The

Continued

financial picture involves income from the mother's Social Security of \$81.00 per month and \$20.00 a month from a roomer in her home; the patient herself receives \$67.00 a month Social Security. Interestingly, the mother told me several times that her daughter had had no seizures during her six years at Cambridge. The patient's routine at home involves mostly watching television. She occasionally dries dishes and sometimes tries to read TV magazines but has trouble with the words.

The current trouble according to the mother includes both seizures and uncontrolled temper outbursts, which appear to be unrelated to each other. Her temper outbursts consist of screaming, shouting, and throwing things. Some of the incidents that cause her to become angry are either her mother's difficulty in hearing or her failure to understand. Also she accuses her mother of being partial to the other siblings, and there is a tendency for her to be suspicious of people. The patient declared emphatically that she never wants to return to Cambridge. One has the impression that she is attempting to control her mother by means of the temper tantrums. Unfortunately the home environment is not well enough designed to provide adequate control of the patient.

Mrs. Kathryn Wilcox:*

While the father was still living, the patient, being the youngest child, was closely attached to him. When she wanted her way, all she had to do was throw a temper tantrum, and eventually this became a pattern. After she was released from Cambridge, the father was in favor of the patient coming home but the mother was not. Subsequently, the patient was directed into a rehabilitation program and placed in a St. Cloud nursing home. Although she had been trained as a kitchen and dining room helper, she was employed as a nurse's aide at St. Cloud, which may account in part for her inability to be successful in this program.

Dr. Soll:

What are her feelings towards Cambridge now? She said that she never wanted to return there.

Mrs. Wilcox:

She has not really said why. I told her she would never have to worry about that because it was no longer in our district. She expressed a willingness to try Faribault, however.

Dr. Brantner:

It is interesting that the Cambridge commitment was for seizures, whereas commitment now to Faribault is for behavioral reasons.

Mrs. Wilcox:

Originally, this probably should have been a commitment for mental deficiency; however, it was actually epilepsy. This was a problem within our court.

Dr. Brantner:

Is the patient still under commitment?

Mrs. Wilcox:

Yes. There will be no change in commitment. Faribault now accepts voluntary patients, the only problem being space. It is much easier for them to take

*Case worker from Dodge County Welfare Department.

in a patient such as this one, who does not need much care.

Dr. Brantner:

Also I think it could be pointed out to them that not only would she not need much care, but that with her working history at Cambridge she might make a contribution in the kitchen.

Mrs. Wilcox:

I talked with one of the officials at the Faribault Institute and mentioned the fact that if the patient were admitted to Faribault, it should be on the basis of a training program in which she would have some type of job away from her family. Hopefully there would be a better setting there. Perhaps even working in another institution would be a possibility; actually Faribault wouldn't be the last resort. The principal goal would be to supply training and an opportunity to obtain routine medication.

Dr. Brantner:

That is another thing that should be stressed again. According to her psychological evaluation she is not capable of responsibly managing a complicated medication schedule—even a simple one. I would be suspicious of dilantin toxicity, because patients like her are quite capable of forgetting their medication and then having a grand-mal seizure. Afterwards they remember and take yesterday's, today's and tomorrow's medication all at once.

Mrs. Wilcox:

I told the patient that she should take the medications as they are prescribed, changing only with the doctor's orders. She replied that she always asks her mother if she should change it. So she may not be taking the medications as they are set up. This is part of the problem. Another problem is that the roomer in their house is an older brother of the patient and they do not get along well together.

Discussion With Patient's Mother

Dr. Soll: (to the mother)

We have been discussing the problems you are having with your daughter. How do you feel about the situation as it has developed throughout the years?

Mother:

There doesn't seem to be any future for her at home. I thought her seizures might be controlled better. They were for a while, but they came back again.

Dr. Soll:

It is possible that this has something to do with her environment. How do you feel about her remaining at home or going to Faribault?

Mother:

What sort of an institution is that?

Dr. Soll:

There are several places that take care of the patients who have seizures, and the most logical one for her at present would be a hospital like Faribault. There would be several advantages; for example, there are other patients who have similar problems, so she might develop a sense of belonging rather than being different. Also she would receive her medications regularly.

Continued

Mother:

Would they be able to teach her something?

Dr. Soll:

This is another reason for her going there. Mrs. Wilcox said the understanding would be that she definitely be given a training period to develop any talent she might have. Dr. Brantner brought out the point that she already had training in working in the kitchen at Cambridge. This fact plus the fact that she is independent as far as her own self care is concerned would be an asset for the hospital.

Dr. Brantner:

How did you get along when she was not at home with you? Did you miss her?

Mother:

I was kept busy, because I wasn't alone then.

Dr. Brantner:

Did you visit her frequently?

Mother:

Maybe about once every two months.

Dr. Brantner:

Do you think that she missed you while she was in Cambridge?

Mother:

She was always glad to see us, but I really think that, in a way, she was happier there than she is at home. Of course, she wouldn't admit that.

Dr. Brantner:

No, but there is the problem of her temper. Did she show this in Cambridge?

Mother:

I don't know. I know she had one tantrum, but that is the only one that I know of.

Dr. Soll:

Does she take care of most of her medicines now or do you help?

Mother:

No, I give them to her in the morning.

Dr. Soll:

Has she ever taken more medicine than she should?

Mother:

About a month ago she did happen to take a double dose when she went to bed, not intentionally.

Discussion With Patient and Her Mother

Dr. Soll: (to the patient)

How do you feel about living away from home?

Patient:

It would be better to get out and work again, maybe do more things or something. Now I just sit around. There is not much to do. It's just a little town that we live in, that kind of gets on your nerves too.

Dr. Soll:

Do you ever lose your temper?

Patient:

Yes. I probably lose it sometimes when I shouldn't.

(The patient and her mother leave the conference room.)

Mrs. Wilcox:

The mother probably will feel bad, but hospitalization is for the patient's benefit. The mother finds it difficult to express herself.

Dr. Brantner:

The patient says very clearly that she would like to leave home.

Mrs. Wilcox:

After admission to the hospital her medications will be controlled and she will be placed on the training program they have in that institution (Faribault) or then another institution.

Dr. Soll:

It probably would be best to admit her to the neurology ward at the University for a couple of weeks to correct this unsteadiness.

Dr. Brantner:

It will be better for her to be in an institution, for she will never be self-supporting. She will always need some type of institutional care.

The Management

The recommendations of this conference were as follows:

1. The patient should be admitted to the Faribault State Hospital. It was thought that this decision would both alleviate the tensions between the patient and her mother at home as well as give the patient some vocational training and a sense of personal fulfillment while being a contributing member to the hospital community.

2. Before any final decisions are made it was recommended that the patient be admitted to the University Neurology Service both to evaluate the ataxia and to reassure ourselves that she did not incur any injury during her recent falls.

Robert Soll, M.D.
University of Minnesota Hospitals

Participating in the conference were: Dr. Robert Soll, Neurologist; Student Doctor David Cannom; Miss Susan Goodman, Clinical Psychology Trainee; Dr. John Brantner, Associate Professor, Clinical Psychology; Mrs. Janet Johnston, Social Service Department and Mrs. Kathryn Wilcox, case worker from Dodge County Welfare Department.

I do not greatly care whether I have been right or wrong on any point, but I care a good deal about knowing which of the two I have been.—Samuel Butler

I have always considered that the substitution of the internal combustion engine for the horse marked a very gloomy milestone in the progress of mankind.

Continuation Course in Neurological Emergencies November 8-10, 1967

A continuation course in Neurological Emergencies will be presented by the University of Minnesota from November 8 to 10, 1967, at the Nolte Center for Continuing Education. This course is designed to present material concerning emergencies of the neurological system and the diagnostic and therapeutic methods of managing them. The program is listed below.

Guest speakers will be DOCTORS DAVID D. DALY, Professor and Chairman, Department of Neurology, University of Texas, Southwestern Medical School, Dallas, Texas; and THOMAS R. H. JOHNS, Professor of Neurology, University of Virginia School of Medicine, Charlottesville, Virginia.

The course will be presented under the direction of DOCTORS A. B. BAKER, Professor and Director, Division of Neurology; and ROBERT W. SOLL, Instructor, Division of Neurology. The remainder of the faculty will include members of the faculties of the University of Minnesota Medical School and the Mayo Graduate School of Medicine.

The Barber's Pole

The barber's pole began its career in the Middle Ages, when the art of surgery and the trade of barber were combined. Blood-letting was then a great cure-all: a vein in the arm was opened and the patient was given a stick or pole to grasp tightly, thus making the blood flow more freely. When not in use, the stick was hung outside the shop, with a white bandage wound around it in a spiral ready for use—indicating that a surgeon was available. But the sight of the gory pole was discouraging to the squeamish, so in time the barbers displayed a pole painted red and white, instead of that actually used in the operation.

THERE'S A FORMULATION FOR EVERY COUGHING NEED

All the Robitussins contain glyceryl guaiacolate, the outstanding expectorant agent that greatly increases the output of lower respiratory tract fluid. Increased RTF volume exerts a demulcent effect on the tracheo-bronchial mucosa, promotes ciliary action, and makes thick, inspissated mucus less viscid and easier to raise.

For coughs of colds and "flu"

ROBITUSSIN®

Each 5 cc. contains:

Glyceryl guaiacolate 100 mg.
Alcohol, 3.5%

For unproductive allergic coughs

ROBITUSSIN® A-C

Each 5 cc. contains:

Glyceryl guaiacolate 100 mg.
Pheniramine maleate 7.5 mg.
Codeine phosphate 10.0 mg.
(warning: may be habit forming)
Alcohol, 3.5%

Non-narcotic for 6-8 hour cough control

ROBITUSSIN®-DM

Each 5 cc. contains:

Glyceryl guaiacolate 100 mg.
Dextromethorphan hydrobromide . 15.0 mg.
Alcohol, 1.4%

New! Clears sinuses and nasal stuffiness as it relieves cough

ROBITUSSIN®-PE

Each 5 cc. contains:

Glyceryl guaiacolate 100 mg.
Phenylephrine hydrochloride . . . 10.0 mg.
Alcohol, 1.4%

Clinical Path Conference

Dyspnea and Acute Pneumonic Infiltration

Dr. Robert L. Strom:*

Case Report

A 67-year-old white male was hospitalized at Hennepin County General Hospital because of dyspnea. An emergency room chest x-ray 18 months previously had been interpreted as showing generalized pulmonary fibrosis. Six months previously he had been hospitalized elsewhere and an extensive pulmonary evaluation had confirmed the diagnosis of idiopathic pulmonary fibrosis. Multiple sputum cultures for tuberculosis and fungi showed no growth. A complement fixation test for histoplasmosis showed no titer. Sputum smears for malignant cells were negative.

On admission to Hennepin County General Hospital his dyspnea was so severe that his activity was limited to bed rest. A persistent cough was productive of a cup of white to creamy sputum per day. He was unable to lie flat because of shortness of breath. Hemoptysis, chest pain, chills, fever and edema were specifically denied.

The patient had been hospitalized two years previously with anterior septal myocardial infarction and had required digitalis and aminophyllin since that time. There was a history of heavy cigarette smoking for many years; however, alcohol had been used only in moderation.

Physical Examination

Physical examination revealed: temperature 98.6°F., pulse 140 per minute, blood pressure 130/90, and respirations 40/min. The patient was markedly dyspneic at rest and cyanotic; his neck veins were not distended. The chest had an increased anterior posterior diameter and showed poor expansion with deep inspiration. Both lung bases were dull to percussion, though rales were audible bilaterally to midscapular level. The breath sounds and heart sounds were distant. There was marked clubbing of the fingers and toes and advanced body wasting. The liver was palpable two fingerbreadths below the costal margin.

Physical and Laboratory Studies

The circulation time (arm to tongue) was 16 seconds and the venous pressure, 11 cm. of saline. A measured vital capacity was 1000 cc. total with 700 cc. expired in one second.

Laboratory studies included a hemoglobin of 15.1 Gm. per 100 ml., a white blood cell count of 10,200 mm³ with 84% neutrophils. The urinalysis was normal. An erythrocyte sedimentation rate (Westergren) was 18 mm. per hour and the prothrombin time 13.7 seconds. A fasting blood sugar was 128 mg. %, BUN 11 mg. %, serum sodium 135 mEq/L, potassium 5 mEq/L, CO₂ combining power 30 mEq/L and chloride 98 mEq/L. Cultures of the sputum showed a mixed flora, and two sputum smears for malignant cells were negative.

*Associate Pathologist, Hennepin County General Hospital.

Continued

A chest x-ray showed a bilateral dense pneumonic infiltration with some superimposed pneumonia. The patient remained afebrile the first few hospital days although rales and cyanosis persisted. On the sixth hospital day, increased respiratory distress was noted; the patient became cyanotic and apneic.

Treatment

Treatment included intermittent positive pressure breathing, aminophyllin 250 mg., librium 10 mg., and Keflin 4 Gm. daily. The blood pressure was maintained with Isuprel and solu-cortef. An electrocardiogram showed paroxysmal atrial tachycardia with a variable block. Cardioversion was accomplished and a tracheostomy performed. Isoniazid 100 mg. t.i.d. and para-aminosalicylic acid 2 Gm. q.6.h. were initiated.

On the seventh hospital day the $p\text{CO}_2$ was 45 mm.Hg., and the bicarbonate 36 mEq/L. By the 15th hospital day, the respiratory rate was 65 per minute. The patient suddenly expired shortly after receiving aminophyllin 150 mg. intravenously.

Discussion

Dr. Thomas Lowry:*

I feel very fortunate in having looked at the chest x-rays of this patient, since the protocol does not reflect the severity of the pneumonic infiltration. Throughout the whole story dyspnea is the predominant symptom. In spite of all attempts at supportive measures, the dyspnea was rapidly progressive. The protocol states that he was short of breath for at least six months. On the other hand, he was seen at the Emergency Room approximately 18 months earlier in March 1965 and had a chest x-ray taken. There is no information as to his symptomatology at that time. On his previous hospitalizations he had been fairly well studied and was dismissed with a diagnosis of idiopathic pulmonary fibrosis.

Inhalants

I think whenever you see someone with pretty diffuse fibrosis in the lungs, you would like to know something about his previous occupation. Nothing is said about it and I assume he was not exposed to such things as asbestos, silica, beryllium and the other inhalants that are known to produce an x-ray picture of diffuse fibrosis. The patient arrived here in early December and lived approximately two weeks. During this time he was never well enough for a proper medical evaluation. If he had had some planograms to really shoot through the pneumonic density, we might have a better idea what there was there. Nonetheless, this man was critically ill and remained so in spite of what was done for him.

Significant Negative Findings

His major complaints on this admission were dyspnea and productive cough. There were several important negative findings. He was said very definitely to have no fever, chills, or hemoptysis. With this much disease in his lung, I consider those findings a little surprising; but nevertheless there they are. He was unable to lie flat because of shortness of breath. I think with that much lung disease, one cannot interpret orthopnea as indicative of left heart failure. The patient needs all the mechanical advantage that he can get in the use of his accessory muscles in breathing.

The physical findings which appear to me to be of importance are the tremendously rapid pulse and respiration with a normal blood pressure. The absence of heart failure is notable. Dullness at his lung bases could have been signs of fluid or atelectasis. The rales over his lower lungs fit with the large amount of white or creamy sputum produced.

*Consultant in Internal Medicine, Hennepin County General Hospital.

Restrictive Respiratory Difficulty

The venous pressure and circulation time confirm the absence of heart failure. The vital capacity readings total was 1000 cc. and the one second was 700 cc. If you figure this out mathematically and allow the patient half a second to inhale, he cannot possibly breathe out more than 700 cc. in one second. I think we have to assume that most of his respiratory difficulty was restrictive rather than obstructive. There were no wheezes or evidence that he was having much trouble getting breath out.

The usual laboratory findings are not particularly helpful here. I am going to disregard the blood sugar of 128 mg.% because I do not believe it fits with anything else. The CO₂ combining power and serum bicarbonate are considerably elevated with a high normal pH. We can assume that he was hypoxic, but no oxygen determination was made.

Dr. S. H. Tsai:*

Perhaps we should start with the first x-ray in March of 1965 (Figure 1). At that time there was an area of infiltration with some fibrous strands in the left upper lobe in addition to some very fine nodulation in the right and left lower lung fields. This was the beginning of the disease process. The heart also appears enlarged. Then after a year and nine-month interval in December

*Chief of Radiology, Hennepin County General Hospital.

Fig. 1—Chest roentgenogram of March 1965 with nodular infiltrate (arrow) in left upper lung field.

Continued

1966 (Figure 2) we have very extensive consolidation of both the upper and mid lung fields. We do not see the right upper lobe take-off or the left main stem bronchus. On serial films the heavy bilateral infiltration persisted until the time of his death in mid-December with only minimal variation due to exposure technique.

Dr. Lowry:

The patient received various antibiotics without any apparent improvement, and shortly after that he was placed on steroids and isoniazid. I would assume that the isoniazid was used strictly as a protective measure and not because anyone thought he had tuberculosis. The rapid course appears incompatible with the diagnosis of tuberculosis. After his tracheostomy he had assisted respirations for the remainder of his life. During part of that time his respiratory rate was 65 and all I can say is that my hat is off to anyone who can make a Bird respirator coincide with that rapid a respiratory rate in a patient. My hunch would be that the patient was fighting the Bird respirator as much as he was getting any help from it. I do not think you can assist respiration with a tracheostomy tube when the patient is already breathing 65 per minute.

I am not going to ask to see the electrocardiograms. He is said to have had a myocardial infarction, and this probably accounts for his slight cardiac enlargement. He had a bout of arrhythmia which was controlled without too much difficulty. I cannot ascribe any particular significance to his expiring

Fig. 2—Chest roentgenogram of December 1966 with diffuse pneumonic infiltrate.

while receiving aminophyllin. I think he simply ran out of breathing space and died.

Differential Diagnosis

Now, what are the likely causes of this illness? First of all, I would like to postulate that this man developed something new between 1965 and 1966. I do not think it was the same disease as before unless the small infiltrate in the left upper lobe is an early bronchogenic carcinoma which extended to involve the left mainstem bronchus and part of the right bronchus. I think he had something new, which had to be malignant. The course was much too rapid for other disease processes. His respiratory impairment appears primarily restrictive. *Progressive fibrosis and emphysema* should have advanced much more slowly than this and should theoretically have produced some right heart failure during the terminal course. In this instance the lungs were simply filled up until he had nothing left with which to breathe. I think that *pneumonia superimposed on pulmonary fibrosis* is an untenable diagnosis. He had no fever or significant response to antibiotic treatment. I considered some of the more exotic conditions. The disease course of *sarcoidosis* or the *Hamman-Rich syndrome* does not progress this rapidly. *Wegner's granulomatosis* is unlikely in the absence of upper respiratory granulomas or multi-system disease. Alveolar proteinosis would have run a slower course and been less malignant and rapid in its final conclusion. I have to say in closing that this was an inexorable, rapid and lethal obliteration of pulmonary air space and had to be some type of cancer. The appearance is perfectly compatible with an alveolar cell carcinoma which often has a multicentric origin and a variable x-ray picture. Usually, however, the course of that disease is not this rapid. I am more impressed with the possibility that this was a bronchogenic carcinoma that spread along the bronchi and closed them off until finally the airway was obliterated.

Clinical diagnosis:

1. Bronchogenic carcinoma of the lung with hilar involvement.
2. Healed myocardial infarction with cardiomegaly.

Pathology

Dr. Strom:

Cardiac Findings

Since the lung was the area of major interest, I will leave that to the last and comment on some of the other post-mortem findings. On opening the chest cavity, the pericardial sac was obliterated with fibrous adhesions. These were nonconstricting and were likely related to his previous myocardial infarction. His heart weight was 420 grams and there was occlusion of the left anterior descending branch of the coronary artery with an old anterior septal myocardial infarction involving the subendocardial region.

Intraperitoneal Findings

The liver showed changes of passive congestion and there was a small recent splenic infarction. Two depressed scars were present in the cortical portions of the right kidney, perhaps related to an embolic phenomenon during the myocardial infarction two years previously. The gastrointestinal tract was

Continued

entirely normal throughout. I think this is important, because we searched the gastrointestinal tract very closely in this case for possible gastrointestinal primary malignancy.

Pulmonary Findings

The process in the lungs held our major interest. The lungs were exceedingly heavy, with considerable fibrotic peel over their surfaces. I believe the degree of pleural thickening might have contributed to the extensive pulmonary x-ray findings. Both lungs were firm to palpation, and the apices were relatively spared of the process as opposed to the more dependent portions of the lungs. The cut surface of the lung showed multiple yellow-white mucoid tumor nodules and infiltrations, some of which had a lobar distribution. However, in the left apical posterior segment there was a 2½ cm. confluent necrotic mass. The localized nodule on the chest x-ray in 1965 would likely conform to this density in the left upper lobe. It is very difficult at times to differentiate between a peripheral bronchogenic adenocarcinoma and a terminal bronchiolar carcinoma or alveolar cell carcinoma. In this instance there were no distinct metastases to other organs and no evidence of tumor in the hilar lymph nodes, although the nodes were somewhat enlarged. Therefore we prefer to classify this as a case of alveolar cell carcinoma or terminal bronchiolar carcinoma with widespread lobar involvement. Heavy mucous plugs were present in the tracheobronchial tree, and there may have been some terminal acute bronchitis as well.

The histology of the tumor nodules is rather interesting in that the histologic cell type is the mature columnar mucus-secreting cell. This is an unusual pattern for alveolar cell carcinoma. The microscopic picture in Figure 3 is characteristic of a mucus-producing alveolar cell carcinoma. The general topography suggests that the mucus-secreting epithelium was laid down around the periphery of the alveolus itself and perhaps did not disrupt the terminal alveolar structure too significantly. Such tall columnar epithelium is much more frequently observed in metastatic carcinomas, particularly from the gastrointestinal tract. Carcinoma of the colon or an occult primary in the

Fig. 3—Alveolar cell carcinoma of the lung. Note tall columnar mucous-secreting epithelium lining alveolar spaces.

stomach can metastasize to the lungs and give this histologic appearance. For this reason, we studied the stomach very closely and were unable to demonstrate a primary lesion in the gastrointestinal tract.

Retrospective Findings

I went back and reviewed the sputum cytologies on this patient to see if we had missed something. It is said that alveolar cell carcinoma is easily diagnosed on sputum cytology. Frequently the pulmonary cytology of alveolar cell carcinoma reveals clumps of uniform sized cells with an altered nuclear cytoplasmic ratio and rounded dark chromatin with prominent nucleoli. It is more unusual when an alveolar cell carcinoma presents with a mucus-secreting tall columnar type of epithelium such as we have seen in this case. In reviewing this patient's sputum, I felt the cytology was rather poorly preserved. Many macrophage* type cells were observed together with some tall columnar type epithelium. As you can see (Figure 3), this is a rather mature type of bronchial epithelium similar to that seen in inflammatory conditions of the bronchi. The degree of fibrosis within the lung parenchyma itself does not suggest that this could be a Hamman-Rich syndrome with epithelial proliferation. I think the findings are quite consistent with a mucus-producing type of alveolar cell carcinoma of the lung.

Anatomic diagnosis:

1. Mucus-producing alveolar cell carcinoma of the lungs.
2. Old myocardial infarction.
3. Cardiomegaly and adhesive pericarditis.
4. Old renal infarctions.
5. Recent infarct of the spleen.

Dr. Lowry:

We often think of carcinoma of the lungs as metastasizing distantly and we often forget that the common site for metastases is the other lung. Metastases of bronchogenic carcinoma to the other lung are by no means infrequent. To me, the clue in this case, and at one point I was certainly looking for it, is the accelerated terminal course.

Dr. Tsai:

Returning to that chest x-ray in March of 1965, I am sure the density in the left upper lobe was the beginning of the disease process, and the fine nodularity was likely tumor cells starting in the alveoli. Dr. Leo Rigler was discussing alveolar cell carcinoma at a recent meeting and showed a series of similar cases with a fibrous band extending into the lesion.

Dr. Strom:

The localized nodule on the x-ray in 1965 would likely conform to the density in the left upper lobe that we observed at autopsy. This was a necrotic nodule which seemed to be a possible focus from which the remainder of the tumor developed.

Robert L. Strom, M.D.

She doesn't feel she "suffers" from hypertension

**Butiserpazide® lowers blood pressure
so smoothly that patients are often untroubled
by either disease *or* therapy**

By switching patients to BUTISERPAZIDE you may be able to free them of much of the burden of hypertension. Clinical comparisons have shown that many respond with (1) smooth, uniform lowering of blood pressure¹...at times to levels *below* those attained with previous therapy²; (2) "striking" improvement in such symptoms as headache, nervousness, palpitation and dizziness²; plus

(3) "...lowered incidence of drug side effects."²

And there's an added advantage: the usual dosage is just 1 tablet once or twice daily, often without need for supplementary therapy. (BUTISERPAZIDE provides not only hypotensive and diuretic action, but a mildly sedative effect as well.) Isn't this the way to take the suffering out of hypertension?

You have a choice of 2 strengths:

Butiserpazide®-25

Prestabs®* Tablets

in mild to moderate cases, often effective at half the usual thiazide or thiazide/reserpine dosage.

BUTISOL® (butabarbital) 30 mg. (½ gr.)†;
Hydrochlorothiazide 25 mg. (¾ gr.); Reserpine 0.1 mg.

Butiserpazide®-50

Prestabs®* Tablets

controls many moderate to severe cases without any need for ganglionic blockers, or other more potent agents; if such agents are needed, their dosage can be cut in half.

BUTISOL® (butabarbital) 30 mg. (½ gr.)†;
Hydrochlorothiazide 50 mg. (¾ gr.); Reserpine 0.1 mg.

*15 mg. of Butisol (butabarbital), plus the other ingredients, in outer layer; 15 mg. of Butisol (butabarbital) in a specially coated core for delayed action, to approximately equalize duration of action for all components.

Contraindicated in presence of renal impairment, peptic ulcer, ulcerative colitis, or mental depression, and in patients with porphyria or those sensitive to any component. **Warning:** Coated potassium tablets, sometimes administered in conjunction with anti-hypertensive therapy, may be associated with small bowel lesions which have led to obstruction hemorrhage, and perforation. Surgery has been required and deaths have occurred. Such tablets should be used only when indicated and when adequate dietary supplementation is not practical. They should be discontinued immediately if abdominal pain, distention, nausea, vomiting or gastrointestinal bleeding occur. **Precautions:** Exercise caution in hepatic disease, diabetes, surgery, coronary artery disease, epilepsy, E.S.T., and in patients receiving digitalis. **Side Effects:** Electrolyte imbalance, hyponatremia, hypochloremic alkalosis and/or hypokalemia, hyper-

uricemia and gout, bradycardia, drowsiness, skin rashes, hangover, systemic disturbances, weakness, leg cramps, diarrhea, epistaxis, dizziness, urticaria, dry itching skin, nausea, vomiting, palpitation, superficial skin bruises, headache, dehydration, paresthesias, photosensitivity, pancreatitis, jaundice, xanthopsia, thrombocytopenia, leukopenia, agranulocytosis, aplastic anemia, nasal congestion, hypotension, lassitude, loose stools, anorexia, bizarre dreams, peptic ulcer, ulcerative colitis, mental depression. (Ammonium chloride, which may be administered to reverse hypochloremic alkalosis, should not be given to patients with hepatic disease.) **Before prescribing or administering, see package insert. †Warning:** May be habit forming. **Usual Adult Dosage:** Butiserpazide®-25 or Butiserpazide®-50: 1 tablet daily or b.i.d. **References:** 1. Johnson, H. J., Jr.: *Penna. M. J.*: 67:35, 1964. 2. Coodley, E. L.: *Curr. Ther. Res.* 4:460, 1962.

McNEIL

McNEIL LABORATORIES, INC.,
FORT WASHINGTON, PA.

Diagnosis:

**cystitis?
pyelonephritis?
pyelitis?
urethritis?
prostatitis?**

**in any case,
usually gram-negative***

Therapy:

two 500 mg. Caplets® q.i.c.
(initial adult dose)

Indications: Urinary tract infections caused by gram-negative and some gram-positive organisms.

Side effects: Mainly mild, transient gastrointestinal disturbances; in occasional instances, drowsiness, fatigue, pruritus, rash, urticaria, mild eosinophilia, reversible subjective visual disturbances (overbrightness of lights, change in visual color perception, difficulty in focusing, decrease in visual acuity and double vision), and reversible photosensitivity reactions. Marked overdosage, coupled with certain predisposing factors, has produced brief convulsions in a few patients.

Precautions: As with all new drugs, blood and liver function tests are advisable during prolonged treatment. Pending further experience, like most chemotherapeutic agents, this drug should not be given in the first trimester of pregnancy. It must be used cautiously in patients with liver disease or severe impairment of kidney function. Because photosensitivity reactions have occurred in a small number of cases, patients should be cautioned to avoid unnecessary exposure to direct sunlight while receiving NegGram, and if a reaction occurs, therapy should be discontinued. The dosage recommended for adults and children should not arbitrarily be doubled unless under the careful supervision of a physician. Bacterial resistance may develop.

When testing the urine for glucose in patients receiving NegGram, Clinistix® Reagent Strips or Tes-Tape® should be used since other reagents give a false-positive reaction.

Dosage: Adults: Four Gm. daily by mouth (2 Caplets® of 500 mg. four times daily) for one to two weeks. Thereafter, if prolonged treatment is indicated, the dosage may be reduced to two Gm. daily. Children may be given approximately 25 mg. per pound of body weight per day, administered in divided doses. The dosage recommended above for adults and children should not arbitrarily be doubled unless under the careful supervision of a physician. Until further experience is gained, infants under 1 month should not be treated with the drug.

How supplied: Buff-colored, scored Caplets® of 500 mg. for adults, conveniently available in bottles of 56 (sufficient for one full week of therapy) and in bottles of 1000. 250 mg. for children, available in bottles of 56 and 1000.

Untoward Reactions Associated with Antimicrobial Therapy

Part II. Cardiovascular, Respiratory,
Gastrointestinal, Hematopoietic, and
Genitourinary Reactions*

Hematopoietic

EOSINOPHILIA is frequently observed, is sometimes pronounced, and can be caused by several, if not all, antimicrobial drugs. On occasion, methicillin, oxacillin, novobiocin, lincomycin, colistin, cephalothin, amphotericin B, and griseofulvin have caused transient leukopenia. Another interesting complication involving the hematopoietic system is the acute, self-limited hemolytic anemia that occurs in certain individuals after the administration of penicillin G, especially when large amounts are given for prolonged periods, as reported by Van Arsdel and Gilliland.²⁰ Certain other individuals in whom acute hemolytic anemia develops have red blood cells that are deficient in the enzyme glucose-6-phosphate dehydrogenase. This biochemical peculiarity is genetically determined, and the defect may remain undetected until such individuals are exposed to one of the oxidant drugs. The sulfonamides, as well as nitrofurantoin, may cause anemia via this mechanism. In this type of anemia hemolysis of the older erythrocytes occurs, whereas the younger erythrocytes remain resistant; hence the acute self-limited course. Survival time of the red cells is reduced to several days, and hemolysis along with reticulocytosis and hemoglobinuria may occur.

The outstanding untoward reaction after therapy with chloramphenicol is, beyond a doubt, bone marrow depression. In a nationwide survey in 1954, a total of 1,167 patients with blood dyscrasias was noted, and 29 of the patients had received chloramphenicol as the sole drug. Of the 29 patients, 17 were less than 10 years of age and

Caucasian girls predominated two to one. Eighty-eight other patients had received chloramphenicol in addition to other drugs. Of the patients with blood dyscrasias in which chloramphenicol was implicated, 68% had aplastic anemia, and most of these patients had received intermittent courses of therapy. An increased incidence of chloramphenicol-induced marrow depression may also occur in patients with hepatic or renal insufficiency. Hematotoxicity is more likely to occur when levels of chloramphenicol in the blood are sustained at 25 µg/ml. or higher. It is variously estimated that the incidence of chloramphenicol-induced aplastic anemia is 1 in 100,000 to 1 in 800,000, with a mortality rate of 50%. Today, with the availability of various effective anti-staphylococcal agents, chloramphenicol probably should not have a routine place in the management of such disease but should be limited to selected gram-negative bacillary infections, especially those due to *Salmonella typhosa*.

Unfortunately, there is no single laboratory procedure that immediately identifies impending chloramphenicol-induced blood dyscrasias. Also, detection of the complication and stopping administration of chloramphenicol may not prevent relentless progression to aplastic anemia. In addition to reticulocytopenia and increased values for serum iron, there are other indices of chloramphenicol's interference with iron metabolism. These include an increase in saturation of iron-binding globulins, a delayed clearance of plasma iron, and a failure of radioactive iron to be incorporated into erythrocytes.

In some cases at least, chloramphenicol-induced suppression of the marrow may represent an accentuated normal response to the drug, because

Continued

*See Part I, Minnesota Med 50:1393, 1967.

mild reversible changes are not rare and large doses given for prolonged periods cause arrest of maturation in most subjects. The metabolic handling of chloramphenicol has been studied in patients who have recovered from chloramphenicol-induced suppression of the marrow; the drug was detoxified and excreted by them in a normal manner. Therefore, hematotoxicity due to chloramphenicol is not invariably a hypersensitivity reaction.

Some data have been interpreted as indicating that L-phenylalanine given orally in amounts of 100 mg/kg. of body weight per day may ameliorate chloramphenicol-induced hematotoxicity, but other workers disagree.²¹

Use of the anabolic drug, oxymetholone, may stimulate regeneration of the bone marrow.

Antimicrobial agents, in addition to chloramphenicol, that may be associated with significant blood dyscrasias are the sulfonamides, ristocetin, and less frequently streptomycin, the tetracyclines, and novobiocin. Methicillin, amphotericin B, and griseofulvin probably have caused marrow depression. The tetracyclines, ristocetin, and amphotericin B may have a special propensity to cause thrombocytopenia in such cases.

It has been mentioned previously that certain antimicrobial agents, especially when the tetracyclines are given intravenously, may interfere with coagulation of blood. In this regard, some data suggest that griseofulvin may alter the anticoagulant activity of warfarin, and consequently, if these two drugs are being administered concomitantly, it is recommended that the prothrombin time be determined frequently, at least initially.

Genitourinary

Antimicrobial-induced renal complications usually present themselves in a similar fashion, despite the drug responsible, and only regular testing will detect them at their onset. The alarm may be given when proteinuria, cylindruria* or microscopic hematuria is found, and the complication may progress to increases in the concentrations of urea and creatinine in the blood. These complications may occur in patients with normal kidneys, although they are more likely to appear earlier in patients who already have decreased renal function. Usually these untoward effects disappear if administration of the offending antimicrobial drug is discontinued sufficiently early.

The potentially nephrotoxic drugs include streptomycin, dihydrostreptomycin, neomycin, kanamycin, amphotericin B, vancomycin, polymyxin B, colistin, and the sulfonamides. Whether ristocetin is nephrotoxic is debatable. It appears increasingly evident that methicillin is nephrotoxic and, rarely, penicillin G has been nephrotoxic, evidently via the mechanism of allergic vasculitis. One should avoid giving excessive doses of paromomycin (Humatin) because the drug is potentially nephrotoxic. Nalidixic acid has resulted in increased azotemia. Increased azotemia also has followed administration of cephalothin, and on occasion the azotemia may be severe enough to be suggestive that in the future the drug may be classed as nephrotoxic. Also, rarely, patients who had normal renal function prior to treatment with cephalothin have experienced azotemia while receiving the drug. Retention of these drugs by previously damaged kidneys may lead to nephrotoxic serum concentrations. Also such factors as dehydration, hypotension, conjoint use of other nephrotoxic drugs, infancy, and advanced age may abet the occurrence of antibiotic-induced nephrotoxicity. From the histologic standpoint, as a generalization, the nephropathies are characterized by necrosis and desquamation of the convoluted tubules, but biopsy has revealed interstitial nephritis in some cases.

Gross,²² as well as Frimpter and associates,²³ reported patients with a reversible type of Fanconi syndrome resulting from ingestion of outdated or degraded tetracyclines. Dehydration, vomiting, muscle weakness, polydipsia, polyuria, glycosuria with a normal blood sugar, metabolic acidosis, proteinuria (sometimes of the Bence Jones type), aminoaciduria, hypokalemia, and hypocalcemia may occur. These complications may be important considerations to any physician who uses professional samples for his personal use.

Castell and Sparks²⁴ described an isolated defect of renal tubular function manifested by polyuria and hyposthenuria after ingestion of demethylchlortetracycline (Declomycin); this example of so-called nephrogenic diabetes insipidus appears to be a reversible effect of the intact drug and unrelated to excessive dosage. The tetracyclines, via their antianabolic effect in patients with underlying renal disease, may increase the degree of azotemia. These drugs may also ad-

*See Test Your Word Score Page 1513.

versely affect the kidneys via the "hepatorenal syndrome" in patients in whom the drugs have caused hepatotoxicity.

As noted under respiratory reactions, certain organisms, such as *Pseudomonas*, are referred to as "water bacilli," indicating their frequent presence in various fluids and on medical instruments exposed to fluids. This residence in solutions explains some iatrogenic urinary infections, in which the urologist inadvertently introduces fluids laden with *Pseudomonas* into the patient's bladder during cystoscopy and allied procedures. As previously noted, infection with these "water bacilli" is abetted if the patient is receiving an agent, such as a penicillin, to which the organisms are resistant.

When a tetracycline is added to solutions employed in peritoneal dialysis, the possibility of an untoward effect of the antibiotic should be considered. In markedly azotemic patients, levels in serum may approach the therapeutic range within 15 to 20 hours.

Gross hematuria is rarely an untoward reaction associated with antimicrobial therapy, but it has occurred on administration of the sulfonamides, chloramphenicol, and ristocetin.

During pregnancy, one should be reticent to employ the tetracyclines because of possible untoward reactions, both in the mother and in the newborn baby. As aforementioned, the tetracyclines can cause serious hepatotoxicity in pregnant women.

Administration of a tetracycline during odontogenesis may be associated with discoloration and hypoplasia of primary and secondary teeth, the degree of discoloration being related to the dose. Apparently the drug is incorporated in the enamel as a calcium orthophosphate complex and changes slowly from an ultraviolet fluorescing bright yellow to a non-ultraviolet fluorescing brown.²⁵ Because of these findings, one should be cautious in prescribing these drugs for pregnant women, as well as for children less than four years of age.

Because of their affinity for mineralized tissues, the tetracyclines interfere with the intra-uterine growth of long bones in experimental animals. Via fluorometry, transplacental deposits of the tetracyclines have been noted throughout the human fetal skeleton; in these cases, there is reversible depression of skeletal growth on short-term administration of the drugs.

The possibility of cataract formation in infants of mothers given a tetracycline during pregnancy or breast feeding is suggested but awaits confirmation.

Streptomycin and kanamycin should be used cautiously in pregnant women for fear of inducing ototoxicity in the infant.

Gynecomastia and pigmentation of the genitalia may occur on use of griseofulvin.

Vaginitis or pruritus vaginae may complicate therapy with certain antimicrobial drugs, including use of a tetracycline or lincomycin.

Grand Rounds

Pernicious Anemia and Myxedema as Coexisting Disease

WILLIAM TORP, M. D.
Medical Resident

THE OCCURANCE of anemia in patients with hypothyroidism has long been known but it is only relatively recently that any basis for this association has been established.

Background

In 1893, Byrom Bramwell, in describing the clinical picture of myxedema, stated: "Some anemia is usually present in myxedema; but the alterations in the blood do not present any notable peculiarities."¹ Apparently there are earlier references to this subject; Tudhope and Wilson cite an article by Charcot which appeared in 1881.² The Mayo Clinic published a study in 1923 of associated diseases in 628 cases of pernicious anemia.³ Seven of these patients had thyroid disease.

Means and his associates are usually cited for first describing the occurrence of pernicious anemia and myxedema although other authors had recognized the resemblance of pernicious anemia to that anemia sometimes found in hypothyroidism.⁴⁻⁹

Sturgis reported an excellent hematologic response to liver extract therapy in one patient with myxedema.⁵ He also noted that while the patient had a BMR of -30 before developing anemia, this became normal when the anemia was most severe and then was again markedly abnormal after correction of the anemia. Sturgis felt that the increased metabolic activity of the processes

*Presented as a Medical Grand Rounds at Hennepin County General Hospital, February 7, 1967.

Continued

of the anemia masked the decrease normally seen in myxedema.

Means et al.⁶ reported five cases of myxedema associated with pernicious anemia in 1931. All of their patients were achlorhydric.* Four had the typical responses to liver extract and thyroid medication that one would expect in pernicious anemia and hypothyroidism. The fifth patient was felt to have both diseases but did not have optimal response to the double therapy.

In 1936, Greene discussed the difficulty one might have in differentiating between these two diseases.⁹ He reported three cases, one of which had pernicious anemia and myxedema and the remaining two had myxedema and also close resemblance to pernicious anemia. He stated: "Clinical manifestations of myxedema and pernicious anemia are sufficiently alike to account for the fact that the former disease is frequently mistaken for the latter."

While this paper is limited to the discussion of pernicious anemia and myxedema occurring together it should be noted that this type of anemia has also been associated with thyrotoxicosis. McNicol, in 1961, published a series of 256 cases of pernicious anemia and a like number of controls.¹⁰ Thirteen of the pernicious anemia patients also had a history of thyrotoxicosis while only two of the controls had such a history.

Frequency

Anemia in hypothyroidism is fairly common. Tudhope published a series of 116 patients with primary hypothyroidism who had not been treated for their disease and reported 37 (32%) of them as having anemia.¹¹ Five of these were normocytic and responded well to thyroid alone, thirteen had pernicious anemia, seventeen had a microcytic anemia which required iron therapy and two had a macrocytic anemia other than pernicious anemia. Holboll, in 1936, reported a decreased hemoglobin ("less than 70%") in 13 of 28 hypothyroid patients.¹² Lerman and Means in 1932 reported anemia in 60% of 52 hypothyroid patients.⁷ Tudhope makes the statement that anemia other than iron or B₁₂ deficiency in these patients is quite uncommon.

The frequency with which clinical pernicious anemia occurs in patients with myxedema has been reported as high as 12.3% in a series of 73 patients reported by Tudhope and Wilson¹³ (See Table 1). Doniach and associates reported two series of patients, each made up of 100 hypothyroid patients.¹⁴ One of these series included two cases of pernicious anemia and the other series had eight cases.

TABLE 1*
Incidence of Pernicious Anemia in Hypothyroidism,
Thyrotoxicosis and the General Population

	Total	P.A.	Incidence P.A. (%)
Hypothyroid			
All cases	166	13	7.8
Spontaneous	97	10	10.3
Post thyroidectomy, 1 ¹³¹	67	3	4.3
Thyrotoxicosis	760	9	1.2
General Population (45 years old and over)	12,639	44	0.35

*Tudhope and Wilson, Quart J Med 29:513, 1960.

*See Test Your Word Score Page 1513.

Common Clinical Findings

An interesting aspect of Tudhope's paper is an observation that has also been made by other investigators. He had 73 patients with primary hypothyroidism, nine of whom had clinically evident pernicious anemia.

Gastric Analysis

Fifty-two patients had gastric analysis and 24 were found to have histamine-fast achlorhydria. (Lerman and Means reported achlorhydria in 53% of hypothyroids.)⁷ Eleven of the achlorhydric patients who did not have pernicious anemia had Schilling tests, and seven of these eleven had urinary excretion of less than 10%. All hypothyroid patients with normal gastric acid had normal Schilling tests.

Serum B₁₂

Tudhope also reported seven patients who had subnormal serum B₁₂ levels but no pernicious anemia. He recommends that any hypothyroid patient with achlorhydria should be thoroughly investigated for pernicious anemia and should continue to be followed since he may develop pernicious anemia. It should be re-emphasized that one of these conditions may mask the other and one must look for the coexisting conditions. Tudhope cites one hypothyroid patient who developed angina while being treated with thyroid; medication was stopped. He was found to have pernicious anemia and was treated with vitamin B₁₂ with good hematological response. When thyroid treatment was resumed the patient no longer had angina.²

Immunologic Basis for the Two Diseases

While the relationship of pernicious anemia and thyroid disease was first suggested by Lerman and Means in 1932, the basis for the relationship was not clear until recently when auto-immune antibodies and techniques to allow their study were discovered and developed.

In 1958, Schwartz found intrinsic factor inhibiting substance in the serum of pernicious anemia patients who had been treated with oral intrinsic factor.¹⁵ They found this substance in 16 of the 21 patients. In 1959, Taylor found intrinsic factor antibody in pernicious anemia patients who had not been treated or who had received parenteral treatment only.¹⁶ Schwartz, in 1960, studied 91 patients with pernicious anemia and found intrinsic factor antibody in 36. He was unable to detect this antibody in the serum of 39 control subjects.¹⁷

TABLE 2*
% Positive Complement Fixation Tests

Diagnosis	No.	Body of Stomach	Thyroid	Liver

Hashimoto's	44	29	81	4
Control	100	4	4	0

*Irvine, et al., Brit Med J 2:454, 1962.

Continued

In 1962, Irvine and associates studied patients with pernicious anemia and thyroid disease using complement fixation tests against thyroid and body of the stomach.¹⁸ The two groups of patients cross-reacted as shown in Table 2. It is interesting to note the results of the control subjects and the lack of cross reaction with liver.

Thyroid Antibodies

Thyroid antibodies can be divided into three distinct organ-specific antigen-antibody systems.¹⁹ They all involve normal thyroid constituents and the antibodies migrate with the gamma globulins on electrophoresis. They are: thyroglobulin, a second protein of the acinar colloid, and an antigen in the microsomal fraction of thyroid epithelial cells.

These can be detected by tanned red cell agglutination test, complement fixation, the precipitin test, or immunofluorescence with varying degrees of sensitivity. The tanned red cell agglutination is thought to be the most sensitive of the tests and involves thyroglobulin antibodies. Some time after Irvine demonstrated that 75% of his patients with pernicious anemia gave a positive complement fixation test to a saline extract of gastric mucosa, it was shown by Taylor and by Irvine that the antibody involved was specific for the cytoplasm of the parietal cell.²⁰ More specific methods for detecting intrinsic factor antigen-antibody reactions were also worked out.

In 1962, Markson and Moore studied the incidence of hypothyroidism in 78 pernicious anemia patients, using tests for thyroid antibodies.²¹ One third of the anemia patients had positive results for thyroid antibodies by one of the three tests employed (tanned red cell agglutination, precipitin test or the complement fixation test), while this was true in only 20% of the controls. They felt the tanned red cell agglutination test was the most sensitive of the three tests. In another paper they reported that in patients with pernicious anemia the gastric mucosa antibody was demonstrable in 32%, while complement fixation test for thyroid was positive in 9%. In patients with Hashimoto's disease the gastric mucosa test was positive in 2.5% and the complement fixation test for thyroid antibodies was positive in 74%.²²

Roitt and Doniach studied the incidence of thyroid antibody in normal subjects and in various types of thyroid disease.²³ Using the complement fixation test they were unable to demonstrate any thyroid antibody in 195 controls and, when using the more sensitive tanned red cell agglutination, the test was positive in only ten of 148 controls. On the other hand, in the 101 primary myxedema patients, 83% were positive using one or more tests, and in patients with Hashimoto's thyroiditis 98% had demonstrable circulating antibodies. In further studies with thyroid antibodies these authors report that in a series of pernicious anemia patients who did not show any overt thyroid disease, thyroid antibodies were demonstrable in 45% but in only 13% of controls.²⁴ On the other hand, 83% of patients with pernicious anemia were positive for gastric cytoplasmic antibody, while in Hashimoto's thyroiditis and in thyrotoxicosis the figures were 27% and 33% respectively.

Irvine and associates in 1965 in a preliminary report on the immunological relationship between pernicious anemia and thyroid disease reported a series of 41 cases of pernicious anemia, 75% of which showed antibody against gastric body mucosa and 37%, complement fixing antibody against thyroid.²⁴ In 121 cases of Hashimoto's thyroiditis or primary myxedema, 70% were posi-

tive for complement fixing antibodies against thyroid and 25% showed antibody specific for gastric body mucosa. In a later article Irvine reported that 73% of a group of pernicious anemia patients showed antibody against parietal cells and 55%, antibody to intrinsic factor, while 86% showed either or both of these antibodies.²⁵ It is interesting to note the incidence of antibodies in chronic hypochromic anemia as compared to the controls (Table 3). Other investigators have also made this observation and have suggested that this could be a stage in the process that ultimately results in pernicious anemia.

22,26,27

TABLE 3*
Incidence of Gastric and Thyroid Antibodies in Patients with Pernicious Anemia and Some Related Disorders

Diagnosis	# Cases	PERCENT POSITIVE			
		Gastric		Thyroid	
		Parietal Cell	Intrinsic Factor	Tanned Cells and/or Comp. Fix	Gastric and/or Thyroid
Pernicious anemia	130	73	55	41	90
Latent pernicious anemia	6	100	50	50	100
Chronic hypochromic anemia	55	14	2	12	20
Thyrotoxicosis	302	24	3	48	57
Chronic thyroiditis	258	30	3	78	85
Blood donors (15-65, male and females)	629	5		13	16

*From Irvine, New Engl J Med 273:432, 1965.

Roitt and Doniach did a comparison study of auto-antibodies in pernicious anemia, Hashimoto's and primary myxedema, systemic lupus erythematosus and a group of hospital controls²⁸ (Table 4). This again tends to bear out the specificity of these antibodies and the very high rate of occurrence of both thyroid and gastric parietal cell antibodies in pernicious anemia and myxedema.

TABLE 4*
Comparison of Auto-Antibodies in Pernicious Anemia, Thyroiditis, SLE and a Control Series

	Pernicious Anemia	Hashimoto's & Primary Myxedema	SLE	Hospital Controls
	189 cases	394 cases	106 cases	
Auto-Antibody				
Gastric parietal cell	89%	32%	2%	2-16%
Thyroid cytoplasmic	55%	87%	2%	0-15%
Anti-nuclear factor	11%	11%	100%	0-19%

*From Roitt, et al., Ann New York Acad Sci 124 Pt II:640, 1965.

Jeffries, in attempting to show the immunologic basis for pernicious anemia, did a very interesting experiment in which he treated one patient with prednisone for four months.²⁹ He felt that if this is an immunologic process he should be able to suppress it with steroids. The patient showed a decrease in titer of serum intrinsic factor antibody, a normal B₁₂ absorption and regeneration of gastric glands. Similar experiments by others have not had such favorable results, however.

The familial aspects of pernicious anemia are well known. Doniach and Roitt, in a study of families of patients with pernicious anemia and thyroiditis,^{30,31} found a much greater occurrence of gastric parietal cell antibodies

Continued

and thyroid antibodies among the relatives of these patients than among a control group.

Summary

In the simultaneous occurrence of myxedema and pernicious anemia there are many common clinical and laboratory manifestations. There is also good evidence for an immunologic relationship. Various workers starting with Means and Lerman have pointed out the more than chance coexistence of these two diseases. Tudhope's series of myxedema patients showed the presence of pernicious anemia in 12% of cases. With the development of immunologic techniques in this area, an even closer relationship between the two diseases was noted.

The point is made by many of the investigators that one of these diseases may mask the presence of the other. For a satisfactory clinical response it is necessary to recognize both diseases.

Case Reports

Case 1

This was the second hospital admission for a 33-year-old female patient who presented with an elevated temperature, chills, fever and some recent complaints compatible with orthostatic hypotension. She had a previous history of treatment for anemia and stated that her father was a pernicious anemia patient. She had received psychiatric treatment in the past for schizophrenic reactions. The patient was chronically constipated and had noted cold intolerance.

Physical Examination

Blood pressure 110/70, pulse 90, temperature 101. She was an icteric-appearing white female, with a flattened affect. Her hair was coarse and straight. The thyroid was easily palpable and soft. There was a low-grade systolic murmur heard best along the left sternal border. The liver was palpable at the right costal margin and the spleen 3 cm. below the left costal margin. The skin was dry. The tendon reflexes showed a slow relaxation phase.

Hospital Course

Hemoglobin on admission was 6.1 Gm. with a wbc. of 2,600 and a platelet count of 40,000. A bone marrow examination was compatible with pernicious anemia. A Schilling test showed less than 1% excretion. (Report of a bone marrow done 13 years previous to this admission stated that there was no evidence of pernicious anemia and was compatible with iron deficiency. Reticulocyte rose to 28% after starting vitamin B₁₂. Serum iron and percent saturation were below normal, while the iron-binding capacity was normal. Protein-bound iodine was 4.6 and 4.2. Radioactive iodine uptake was 10% and after TSH stimulation 17%. Total thyroxin was in the normal range and BMR was +2. Thyroglobulin auto-antibodies were negative. Gastric analysis showed achlorhydria.

It was felt that the patient was clinically hypothyroid as well as iron and vitamin B₁₂ deficient. She was treated with B₁₂ and iron while in the hospital, her hemoglobin rose to 10 Gm., and she was much improved clinically. Her present hemoglobin is 13.1% with hematocrit of 39%. Thyroid extract therapy was begun and monthly vitamin B₁₂ injections continued.

Case 2

This was the first admission for a 69-year-old patient who complained of weakness, fatigue, malaise, anorexia and weight loss along with paresthesias for one to two months prior to admission. His friends had recently told him that his skin looked yellow. He had previously been in good health.

Physical Examination

Blood pressure 114/60, pulse 100 and regular. He was a moderately obese, irritable,

white male, with a yellow skin color. The sclerae were mildly icteric. Funduscopy examination showed a few flame-shaped hemorrhages. The tongue was pale and smooth. There was a soft systolic heart murmur. Abdomen was negative. Neurological examination showed decreased strength in the extremities along with some decrease in vibratory sense.

Hospital Course

The blood on admission showed hemoglobin of 3.6 Gm., 2,300 wbc. Bone marrow was done on the day of admission and the patient was then given two units of packed red blood cells and was digitalized. He tolerated this quite well and felt much better. The bone marrow was compatible with pernicious anemia and increased iron stores were noted. A Schilling test result was 3% excretion, bilirubin 5.1 total, LDH 1010 and cholesterol 50 mg %. The patient was started on vitamin B₁₂ and had a reticulocyte response to 19% although his hemoglobin did not respond optimally and remained at 6 to 7 Gm. The wbc. and platelet counts rapidly returned to normal. There was no response with folic acid. On the twenty-third hospital day oral iron therapy was started after obtaining serum iron studies. Serum iron was 20 micrograms percent and iron-binding capacity was 136 micrograms percent. His hemoglobin then rose to 10.5 Gm. while in the hospital; three months from the date of his admission the hemoglobin was 14.3. Protein-bound iodine was 3 micrograms percent, radioactive iodine uptake was 10% and after TSH stimulation was 13%. It was felt that the patient was hypothyroid and he was started on thyroid extract with rapid improvement of his clinical state. He is now being maintained on 3 Gm. of thyroid extract and doing well. His hematological picture is normal and stable. Antithyroglobulin titers were normal in this patient.

Minnesota Medicine Cover Photographs

In order to encourage more physicians to submit color slides for use on the cover of MINNESOTA MEDICINE the competition is being discontinued. The picture editor now invites all physician-photographers to send 35 mm. color slides of suitable subjects for consideration as cover pictures. The format must be horizontal because of printing limitations. Pictures highlighting Minnesota seasons, places, and activities will have an automatic advantage. No limit as to the number of slides sent will be set, but all slides should be individually identified. All slides will be returned. Physicians whose pictures are used as covers will be recognized in MINNESOTA MEDICINE. We can use many more pictures than we have received in the past.

Reciprocity

Edible: good to eat, and wholesome to digest, as a worm to a toad, a toad to a snake, a snake to a pig, a pig to a man, and a man to a worm.

—Ambrose Bierce

FREE YOUR PATIENTS from
/ deficient neutralization
/ poor taste
/ burdensome cost
with DICARBOSIL[®] antacid

■ **effective neutralizing power**—Two tablets in vitro¹, provide nearly 2 hours' relief within effective pH range 3 to 5.5.

■ **pleasant taste**—A fresh mint flavor patients continue to enjoy. With Dicarbosil's unique* formulation, chalky after taste is no longer a problem.

■ **exceptional economy**—Due to its high neutralization capacity combined with low cost (about 1¢ or less per tablet), Dicarbosil is within the reach of all patients.

Book Reviews

We are as liable to be corrupted by books, as by companions.—Fielding

ATLAS OF GENERAL SURGERY — Joseph R. Wilder, Second Edition, C. V. Mosby Company, St. Louis.

Any atlas, by the nature of its intent for the briefest and most basic teaching, presents considerable difficulty for any reviewer, who may and most likely has his own concepts which are at some variance with those presented by the author of such a brief work. Perhaps a surgical atlas would never be totally satisfying to an individual reviewer unless it presented many of the various approaches for solving technical surgical problems. If this were undertaken, it would then hardly fulfill the purpose of an atlas.

This particular atlas might well serve its function in a library of hospitals, where interns and residents could examine it, along with other similar works, to obtain some basic fundamentals of technique.

The introductory comments are succinct and appropriately brief for an atlas. Certain emergency procedures are outlined at the beginning, and these are then followed by a catalog of various general procedures most commonly dealt with in a general hospital. Finally, there is a brief section on certain plastic repairs of tendons and peripheral nerves. The drawings are of good size with reasonably adequate detail.

Under the early section of venous cutdown descriptions, it might have been more appropriate to dwell less on the use of the saphenous vein at the ankle as an avenue of intravenous administration, since none of the shortcomings were outlined, and to have devoted some space to the avenues of central venous pressure and rapid infusion, such as the external jugular, the cephalic, or the sub-clavian vein.

The description of a thyroidectomy appears somewhat incomplete in the method of preserving the blood supply to the parathyroids and the method of identification of the recurrent laryngeal nerve. The author apparently prefers the method of parotidectomy utilizing distal pick-up of the VII nerve branches. Many trained in that method have changed to the method of proximal dissection.

The drawings, or the exposition of Cooper's ligament in the hernia repair, do not appear adequately clear, particularly regarding the repair of femoral hernia.

In the section on biliary surgery, one drawing indicates the direction of the knife blade toward the vital structures of the porta. This, however, is perhaps a very minor criticism. For the section on common bile-

duct injury, the methods of its occurrence are quite timely and useful for the student.

The Roux-Y common duct anastomosis employs a direct end-to-end rather than common duct to buttonhole adjacent to the end of the closed jejunum, so that each side of the common duct risks the hazard of the three-directional closure.

The method of perforated peptic ulcer closure involves plication with no note whatever of the standard Graham closure. This would lead the uninitiated into considerable difficulty in attempting to invert or invaginate the frequently wide zones of induration.

Finally, the operations described for gastric cancer and colonic cancer appear to be somewhat deficient or too brief in their emphasis on proper node dissection for malignancies.

MODERN TREATMENT — Treatment of Neuromuscular Disorders by Frank M. Howard, Jr., M.D.; Treatment of Hypoglycemia by Buris R. Boshell, M.D., Harper and Row, March 1966.

Modern Treatment is a bi-monthly paperback published by Harper and Row through the Hoeber Medical Division. Each volume concerns itself with one or two topics with a guest editor and several contributors. The current issue concerns neuromuscular problems edited by Frank M. Howard and hypoglycemia edited by Buris R. Boshell. Although treatment appears prominently on the cover and in the titles, the contributors have not limited themselves to this narrow approach to medicine. I suspect the publishers have chosen the general title of Modern Treatment since naturally everybody is interested in treatment as the lodestone in medicine attracting all physicians. One need not apologize for considering all aspects of a medical problem under "Treatment", since obviously pathophysiology, diagnosis, and the like, are fundamental to treatment. These two topics are somewhat widely disparate, appealing to different sections of the medical profession. However, one can recommend this volume to all physicians who see general medical problems. Hypoglycemia appears in many guises, including psychoneurosis and psychosis. Myasthenia gravis, admittedly not a common disease, may be primarily seen by any practitioner.

Reuben Berman, M.D.
Minneapolis, Minnesota

Sustained circulatory, respiratory and cerebral stimulation for the

(fewer absent doses by
absent-minded patients)

Human volunteer subjects were administered Geroniazol TT tablets with the nicotinic acid component made radioactive with C-14. Plasma and urine samples were analyzed. (See Figures I and II) The radioactive tracer study substantiated the previous clinical evidence that the release of nicotinic acid from the Geroniazol TT tablet produced a gradual rise in plasma levels to a plateau for a total of 12 hours and more.

Such proven sustained activity makes the management of geriatric patients much easier by minimizing the possibility of neglected doses through absent-

mindedness or senile confusion. Therapy *can* be continuous on a daily dose of only one Geroniazol TT tablet every 12 hours.

The gradual release of nicotinic acid in Geroniazol TT will provide the well-known peripheral vasodilatation needed in patients with deficient circulation and with a minimum amount (if any) of "flushing." Also, cerebrovascular circulation is complemented by pentylentetrazol, long-established as a cerebral and respiratory stimulant.

Geroniazol TT improves the typical, unfortunate, signs of senile confusion. Patients become more alert,

aged and debilitated

Fig. 11. Cumulative average urinary excretion of C-14 radioactivity following oral administration of C-14 nicotinic acid tablets. Key: — Group A, one sustained-release tablet containing 150 mg. C-14 nicotinic acid, — Group B, one nonsustained-release tablet containing 50 mg. C-14 nicotinic acid, — Group C, one nonsustained-release tablet containing 50 mg. C-14 nicotinic acid at 0, 4 and 8 hours.

less confused and moody. Personal care, memory, emotional stability, social attention improve. Fatigue, apathy and irritability are reduced.

A prescription for 100 tablets of Geroniazol TT will permit your patients to enjoy the benefits of time-prolonged nicotinic acid/pentylenetetrazol therapy, at an economical price. Dosage is only one tablet every 12 hours.

Contraindications: There are no known contraindications.

Precautions: Exercise caution when treating patients with a low convulsive threshold.

Side Effects: Side effects are rarely encountered, however due to the vasodilatation effect of nicotinic acid, transitory mild nausea, flushing, tingling and pruritus are possible.

Dosage: One tablet every 12 hours.

Supplied: Prescribe bottles of 100 tablets, to take advantage of recent price reduction.

Geroniazol[®] TT

nicotinic acid 150 mg., pentylenetetrazol 300 mg.
Tempotrol[®] Time Controlled Tablet

when bursitis hits a 280-lb. tackle, hit back with Butazolidin alka

Indications: Osteoarthritis, rheumatoid arthritis, rheumatoid spondylitis, psoriatic arthritis, acute gout, painful shoulder (peritendinitis, capsulitis, bursitis and acute arthritis of that joint), acute superficial thrombophlebitis.

Contraindications: Edema; danger of cardiac decompensation; history or symptoms of peptic ulcer; renal, hepatic or cardiac damage; history of drug allergy; history of blood dyscrasia. The drug should not be given when the patient is senile or when other potent drugs are given concurrently. Large doses of Butazolidin alka are contraindicated in glaucoma.

Warning: If coumarin-type anticoagulants are given simultaneously, watch for excessive increase in prothrombin time. Instances of severe bleeding have occurred. Pyrazole compounds may potentiate the pharmacologic action of sulfonyleurea, sulfonamide-type agents and insulin. Carefully observe patients receiving such therapy. Use with great caution in the first trimester of pregnancy.

Precautions: Before prescribing, carefully select patients, avoiding those responsive to routine measures as well as contraindicated patients. Obtain a detailed history and a complete physical and laboratory examination, including a blood count. The patient should not exceed recommended dosage, should be closely supervised and should be warned to discontinue the drug and report immediately if fever, sore throat, or mouth lesions (symptoms of blood dyscrasia); sudden weight gain (water retention); skin reactions; black or tarry stools or other evidence of intestinal hemorrhage occur. Make regular blood counts. Discontinue the drug immediately and institute countermeasures if the white count changes significantly, granulocytes decrease, or immature forms appear. Use greater care in the elderly and in hypertensives.

Adverse Reactions: The most common are nausea, edema and drug rash. Swelling of the ankles or face may be minimized by withholding dietary salt, reduction in dosage or use of diuretics. In elderly patients and in those with hypertension the drug should be discontinued with the appearance of edema. The drug has been associated with peptic ul-

For 280-lb. tackles — or 108-lb. housewives — Butazolidin alka can hasten recovery from the agonizing pain of shoulder bursitis.

It's not for every patient. Check carefully the Contraindications, Warning and Precautions shown below.

And adverse reactions may occur. The most common are nausea, edema and rash. Rarely, agranulocytosis has been reported. All adverse reactions are listed below, too.

Play-for-pay or workaday patients — when they come up with shoulder bursitis and your clinical judgment indicates Butazolidin alka — go with it.

And watch the comeback.

cer and may reactivate a latent peptic ulcer. The patient should be instructed to take doses immediately before or after meals or with milk to minimize gastric upset. Mild drug rashes frequently subside with reduction of dosage. However, rash accompanied by fever or other systemic reactions usually requires withholding medication. Purpuric rash has also been reported. Agranulocytosis, exfoliative dermatitis, Stevens-Johnson syndrome, or a generalized allergic reaction similar to serum sickness may occur and require permanent withdrawal of medication. Stomatitis, salivary gland enlargement, vomiting, vertigo and languor may occur. Leukemia and leukemoid reactions have been reported. While not definitely attributable to the drug, a causal relationship cannot be excluded. Thrombocytopenic purpura and aplastic anemia may occur. Confusional states, agitation, headache, blurred vision, optic neuritis and transient hearing loss have been reported, as have hyperglycemia, hepatitis, jaundice, and several cases of anuria and hematuria. With long-term use, reversible thyroid hyperplasia may occur infrequently. Moderate lowering of the red cell count due to hemodilution may occur.

6509-V(B)R2

Butazolidin[®] alka

Capsules

100 mg. phenylbutazone
100 mg. dried aluminum hydroxide gel
150 mg. magnesium trisilicate
1.25 mg. homatropine methylbromide

Dosage in painful shoulder: Initial: 3 to 6 capsules daily in 3 or 4 equal doses. Trial period: 1 week. Maintenance dosage should not exceed 4 capsules daily; response is often achieved with 1 or 2 capsules daily.

For complete details, please see full prescribing information.

EASTERN WISCONSIN CLINIC in rapidly growing community of 50,000 desires board-eligible or certified physicians in obstetrics and gynecology, pediatrics, orthopedic surgery, urology and otolaryngology. Well-equipped clinic and excellent hospital facilities. Lake shore location offers ample recreational facilities. Attractive financial plan leading to early full partnership. Full expenses paid for applicants invited to interview. Call or write: F. L. Hildebrand, M.D., Riverside Clinic, Menasha, Wisconsin.

EXCELLENT OPPORTUNITY. Established General Practice, sixteen years. Country home, office, equipment available July 1. South Central Minnesota town 12,000. Specializing. Contact A. L. Ourada, M.D., Fairmont, Minnesota. Phone 235-5848.

OFFICE SPACE now available in busy Bloomington. 713 square feet of new space in building with busy group of G.P.'s, dentist and suburban OB-GYN office. Ideal for ophthalmology, ENT or pediatrics. 8040 Penn Avenue South. 888-9211.

WANTED: GP to join clinic serving population area of 12,000. City has new hospital, new clinic building, two nursing homes, new Jr-Sr high school, new swimming pool, rich farming area in Red River Valley. Fishing and hunting nearby; metropolitan city close by. Salary open and partnership if interested. Write or call Warren Clinic, Warren, Minnesota 742-6231, area code 218.

WANTED: General practitioner, to join two G.P.'s well established in north central Minnesota community, 2200 pop., 65 miles from Twin Cities. Excellent office space with lab and X-ray, just opened new hospital, all facilities. Assistantship or partnership. Considerable surgery and obstetrics. Hunting, fishing, golf club. Great opening for interested G.P. WRITE MINNESOTA MEDICINE—381; 375 Jackson, St. Paul, 55101.

GENERAL PRACTITIONER wanted to join well-established practitioner. New clinic building—90 miles east of St. Paul—city of 14,000. Early partnership with full hospital facilities. Ideal location. L. W. Picotte, M.D.; Chippewa Falls, Wisconsin.

INTERNIST AND GENERAL PRACTITIONER wanted to join a five-man clinic group in Minneapolis. Complete laboratory and X-ray with board roentgenologist. Excellent hospital staff associations. Salary arrangement to start with early partnership. Write: MINNESOTA MEDICINE—289; 375 Jackson, St. Paul, 55101.

GENERAL PRACTITIONERS AND INTERNISTS to join eight-man group in fascinating San Francisco. Locum tenens also available. Will meet reasonable salary request. A. J. Franzi, M.D., 3620 Army St., San Francisco, Calif. 94110.

WANTED GENERAL PRACTITIONER, General Surgeon, Obstetrician for active group clinic in Minneapolis suburb. Now six man group including full time surgeon and obstetrician. New clinic facilities and two new hospitals near by. Salary open. Partnership offered after short trial period. Coon Rapids Clinic, 9920 Zilla Street, N.W., Coon Rapids, Minn. 55433.

WANTED: GENERAL SURGEON to fill vacancy with well established eight man group. Beautiful award winning clinic just blocks from new 120 bed hospital. Picturesque community of 15,000 located on the Mississippi River with good recreational facilities, schools and churches. An excellent opportunity in a growing environment. Salary one year, then partnership. Write: Harry Williams, M.D., Medical Block Clinic, Red Wing, Minnesota, or call 507, 388-4751.

GENERAL PRACTITIONER desires position with group or partnership in town of 3000 population or more, preferably within 100 miles radius of Twin Cities. Currently in solo practice including surgery and OB at same location for 12 years. Write: MINNESOTA MEDICINE—383, 375 Jackson, St. Paul, 55101.

WANTED: Young, energetic General Practitioner to join one man clinic. Salary open. Contact: Maurice Meller, M.D., Brainerd Clinic, Brainerd, Minnesota.

INTERNIST, PEDIATRICIAN and OB-gynecologist wanted to join two general surgeons in a rapidly growing practice. Attractive town of 3,000 on large lake 30 miles west of Twin Cities. New 55-bed JCAH hospital with plans for major expansion. Five other physicians in town. No OB-GYN, internist or pediatrician in area. Medical community serves in an area with population of 20,000 to 25,000. Planning to expand into partnership multi-specialty clinic. Call or write: Savaryn Clinic, Waconia, Minnesota 55387. Telephone: 442-2137.

WANTED: Locum Tenens for general practice for February 1968. Salary open. Contact: Maurice Meller, M.D., Brainerd Clinic, Brainerd, Minnesota.

THREE MAN group in North West Wisconsin Resort, State Conservation and Retirement Area needs two more physicians adequately to serve their practice. Facilities offered are three-room physician suites, X-ray and lab under AMT technician, RN-only nursing personnel. New accredited thirty-two bed hospital and forty-six bed nursing home. Deer and duck hunting, fishing within five minutes of town. Internist most needed; generalists welcomed. Will meet any reasonable salary request. Partnership after one year. Write: MINNESOTA MEDICINE—365; 496 Lowry Medical Arts Building, St. Paul 55102.

PHYSICIAN INTERESTED in internal medicine wanted for Medical Service. Starting salary \$12,873 to \$17,221, depending on qualifications. Liberal fringe benefits. Non-discrimination in employment. Contact Chief of Staff, Veterans Administration Hospital, Des Moines, Iowa 50308.

RICHMOND, VIRGINIA 23217

Manufacturers of ethical pharmaceuticals since 1856

WANTED: YOUNG PHYSICIAN for association leading to partnership with four well-established General Practitioners in fast-growing suburb of St. Paul. Excellent clinic facilities in nearly new, partnership owned, well equipped, medical center building. Contact: A. Eugene Muller, M.D., North St. Paul Medical Center, 2579 East 7th Avenue, North St. Paul, Minnesota 55109.

WANTED: PEDIATRICIAN, certified or eligible, to associate with two certified pediatricians in upper mid-west college city of 50,000. Write: MINNESOTA MEDICINE—387, 375 Jackson, St. Paul 55101.

WANTED: ASSOCIATE for young general practitioner. Excellent clinic and hospital facilities. Salary or partnership. Agricultural and resort area, good hunting and fishing. Write: Lewis E. Struthers, M.D., Parker Prairie, Minnesota. Telephone: 218-338-4471 (residence) or 218-338-4371 (clinic).

PHYSICIAN WANTED: G.P. with additional surgical and O.B. experience — desired to associate with two G.P.'s with similar experience in large, well established practice in Central Minnesota. Hospital accredited, 300 bed, open staff, complete services. Salary leading to partnership. Adequate housing in area. Send background information, professional and personal to: MINNESOTA MEDICINE, Box 283, 496 Lowry Medical Arts Bldg., St. Paul, 55102.

MORGAN, MINNESOTA, Wants a General Practitioner. Opportunity to take over a well established practice. Physician recently retired after practicing here for 33 years. Progressive community in the best rural area of Southern Minnesota. New medical clinic building just completed. Call or write M. L. Kuhn, Morgan, Minnesota. Tel. Morgan #73 or #99.

SAN FRANCISCO AREA: G.P.'s and/or Internists to associate with group in fascinating Bay Area; Salary open. Partnership and locum tenens available. A. J. Franz, M.D., 3620 Army St., San Francisco, Calif. 94110.

GENERAL PRACTITIONER OR INTERNIST needed in six man group in Northeastern Minnesota. 38 bed accredited hospital next door to modern clinic, rotating call schedule, over 4 wks. vacation per year, study and sick leave, group paid disability and retirement plans, and full partnership in 6 months. Starting guarantee \$18,000 to \$22,000 with increases to \$26,000 to \$28,000 over 4 years. Ideal opportunity for man desiring association with active group in small community offering good income plus ample time off. Contact Harold B. Leppink, M.D., Community Clinic, Two Harbors, Minnesota. Phone Area 218 834-2171.

WANTED: INTERNIST to enlarge busy internal medicine department in highly successful nine man specialty group. All are board certified. Well equipped lab and x-ray—new 120 bed hospital. Pleasant community of 15,000+ on Mississippi River. Good recreational facilities, not far from Twin Cities. Salary one year then partnership. Write George E. Jackish, M.D. —Interstate Clinic, Red Wing, Minnesota or call 507 388-3503.

GENERAL PRACTITIONER WANTED—Ipswich, S. Dak. pop. 1200 is losing one of two doctors. New \$360,000 Hospital opened Oct. 1965. County seat town & only Medical Center in County of 6,000 pop. Desirable office space available. Good school, good hunting & fishing, no riots, potential practice: Excellent. Call collect or write: Earle T. Crissman, Ipswich, S. Dak. phone—day 5111, night—4551.

Bilateral Vestibular Paralysis Syndrome

Complete loss of vestibular function in man was demonstrated clinically by James in 1882. Clinical features include a staggering gait as well as a broad base when walking in the dark or with eyes closed. There is inability to fix the eyes upon an object while moving the head. With the eyes closed there is complete disorientation in water. Coloric or rotation tests for labyrinthine function show no evidence of vertigo, unsteadiness, nausea, nystagmus, or past pointing. In four cases (Chusid and de Gutierrez-Mahoney) the etiology was attributed to an infectious process including scarlet fever, scrub typhus, and syphilis.

Durham, Robert H. — Encyclopedia of Medical Syndromes
Hoeber Medical Division, Harper and Row, New York

Remedies For Boils

For the cure of boils, beef-suet is applied with salt; but if they are attended with pain, it is melted with oil, and no salt is used. Goat-suet is employed in a similar manner.—Pliny.

Tired or Curious

Men marry because they are tired, women because they are curious. Both are disappointed.—Wilde.

Physician's Diary

The insolent civility of a proud man is, if possible, more shocking than his rudeness could be; because he shows you by his manner, that he thinks it mere condescension in him, and that his goodness alone bestows upon you what you have no pretence to claim.—Chesterfield.

Dr. John L. Juergens, consulting physician in internal medicine at the Mayo Clinic, is the new president of the Minnesota Heart Association. Dr. James H. Kelly, St. Cloud, was elected president-elect; Mr. E. William Quirin, Rochester, second vice-president, Dr. John Fee, St. Paul, secretary; and Dr. John L. Olson, St. Paul, treasurer.

* * *

Dr. Charles A. Neumeister has been re-elected president of the Blue Shield of Minnesota, Dr. Harold Mork, Anoka, was elected to the Board of Directors, and Dr. John G. Lohmann, Pipestone, was elected Treasurer.

* * *

Dr. Robert L. Radke of Montevideo and Dr. Elmer Keithahn, Sleepy Eye, have been reelected to active membership in the American Academy of General Practice, and Dr. Donald E. Wohlrabe, Springfield, and Dr. David R. Holten, Edina, have been elected to active membership in the same Academy.

* * *

Dr. Edward A. Banner, member of the Section of Obstetrics and Gynecology of the Mayo Clinic, was chosen president-elect of the Continental Gynecologic Society at its annual meeting in May.

* * *

Dr. John C. Duffy has been named chief consulting psychiatrist for the Minnesota Residential Treatment Center in Circle Pines.

* * *

Dr. Michael M. Paparella has been appointed head of the Department of Otolaryngology at the University of Minnesota College of Medical Sciences and Dr. Robert Mulhausen, assistant chief of medicine at Veterans Hospital, Minneapolis, has been named assistant dean of the University of Minnesota College of Medical Sciences.

* * *

Dr. John A. Docherty, Medical Director of Anoka State Hospital, accepted an appointment as a full-time member of the Medical Staff at Hennepin County General Hospital and Hennepin County Mental Health Center. This became effective August

16. Dr. Guido H. Schynoll has been appointed Acting Medical Director of the Anoka State Hospital.

* * *

New Location: Dr. David J. Lamusga is now associated with the Mora Clinic in Mora. . . . Dr. A. E. Carlson, Warren physician, has moved to Fargo where he will be senior physician at the Veterans Hospital. . . . Dr. George W. Ibrahim has joined the Lenont-Peterson Clinic in Virginia. . . . Dr. E. P. Bryant has resigned his position on the medical staff of the Faribault State School and will resume his practice on a full-time basis in Ellendale. . . . Dr. Robert Pierce will practice medicine on a part-time basis in Mountain Lake and Heron Lake dividing his time between the two communities. . . . Dr. Mustafa Vidinli has left Roseau for Aurora, Illinois, to do some research work at Northwestern University. . . . Dr. Gerardo A. Crichigno has joined the medical staff at Hastings State Hospital. . . . Dr. O. B. Fesenmaier, Brown County coroner and New Ulm physician, has taken a one-year leave of absence from his medical practice to do graduate work in Los Angeles. . . . Dr. Roger A. Dreyling has joined the Paynesville Community Hospital staff. . . . Dr. W. F. Schamber has left Parkers Prairie to assume duties as staff doctor at the Veterans Hospital in St. Cloud. . . . Dr. Roland Larter has joined the Karlstad Memorial Hospital. . . . Dr. A. H. Field, Burnsville, has accepted a position with the University of Arizona. . . . Dr. Lewis E. Struthers is the new doctor for Parkers Prairie. . . . Dr. Norbert O'Keefe has joined the Quain and Ramstead Clinic in Bismarck. . . . Dr. David Sweet has become associated with Doctors Thayer, Wandke and Kraemer in Fairmont. . . . Dr. Kenneth L. Buresh has joined the Owatonna Clinic. . . . Dr. Gerald Cotton has left Fosston to take up a fellowship in Internal Medicine at the Mayo Graduate School of Medicine. . . . Dr. James Garber has joined the Olmsted Medical Group in Rochester. . . . Dr. A. L. Ourada has left Ceylon to accept a four-year residency training program at St. Paul Ramsey Hospital in St. Paul. . . . Dr. James Terrian has joined the Klefstad Clinic in Greenbush. . . . Dr. Donald Mattson has joined the medical staff of the Lakeland Medical Center in Willmar.

AMA '67 HOUSTON

AMA 21ST CLINICAL CONVENTION • ASTROHALL • HOUSTON, TEXAS • NOVEMBER 26-29, 1967

Plan to attend this year's AMA Clinical Convention in Houston, Texas. Eighteen scientific sessions, four postgraduate courses, breakfast roundtable discussions, color television, and scientific and industrial exhibits will bring you up to date on the latest medical advances. Attend lectures by, and discussions with, our nation's outstanding medical authorities.

Between sessions, enjoy the excellent restaurants, fine shops, visitors' attractions, and mild winter temperatures Houston offers. Mail the enclosed registration and room reservation coupons now, and look forward to an exceptional convention with a holiday plus.

SCIENTIFIC SESSIONS: Cardiovascular Disease; Cardiovascular Surgery; New Cares; Ophthalmology; Geriatrics; Arthritis; Gastroenterology; Cancer; Antibiotics; Endocrinology; General Surgery; Dermatology; Aerospace Medicine; Obstetrics and Gynecology; Psychiatry; Pediatrics; Genitourinary Diseases; and Otolaryngology.

POSTGRADUATE COURSES: Fluid and Electrolyte Balance; Oncology; Cardiovascular Disease; and Obstetrics and Gynecology. Register for these Courses on arrival in Houston at the PG Course Registration booth adjacent to the General Registration area. There is no charge for the Courses, but registration is limited to 200 per Course. The Courses begin promptly at 9 A.M. and 2 P.M. No one will be seated after the Course begins.

BREAKFAST ROUNDTABLE CONFERENCES: Management of Cerebrovascular Insufficiency; Indications and Limitations of Uses of Antibiotics; The Moral and Ethical Aspects of Caring for the Dying Patient; Adolescence, Age of Rebellion, Related Psychiatric Aspects.

COLOR TELEVISION • MEDICAL MOTION PICTURES

• SCIENTIFIC AND INDUSTRIAL EXHIBITS

The complete scientific program, plus forms for advance registration and hotel accommodations, will be featured in JAMA, October 23.

Meetings and Announcements

Our knowledge is the amassed thought and experience of innumerable minds
—Emerson

OCTOBER

Hennepin County Academy of General Practice, October 2, Membership Meeting, Pick-Nicollet Hotel, 6:00 P.M. Social Hour; 6:45 Dinner, 7:45 Business meeting.

St. Louis County Medical Society Executive Committee, St. Luke's Hospital, 6:00 P.M., December 14. Annual Banquet, Kitchi Gammi Club, 7:30 P.M., December 16.

McLeod County Medical Society, December 21.

Minnesota Academy of Ophthalmology and Otolaryngology. No date set as yet.

INFLAMMATION: A cellular fight for life

A SYNTEX REPORT based on recently developed hypotheses about topical corticosteroids, including the cellular theories of inflammation by Thomas F. Dougherty, Ph.D., University of Utah.

You are looking at a fibroblast fighting for life. This cell—one of the most common found in connective tissue—has literally been poisoned by cytotoxins released from other cells that have ruptured. Soon, if the abnormal activity of this fibroblast does not cease, it, too, will rupture and die—one more casualty in the inflammatory wave of destruction precipitated by injury.

Until a short time ago no one had ever witnessed such a scene at the cellular level. Now, through advanced cinemicrographic techniques, it is possible to view and photograph the inflammatory process as produced experimentally in living animal tissue. This method permits new insight into the mechanism of inflammation and the role of corticosteroids in therapeutic management. Equally important, these techniques shed new light on factors that may make one corticosteroid more effective than another—factors that can be correlated with other chemical, biologic, and clinical parameters.

Phase-contrast microscopy showing mast cell before injury.

Mast cell (after injury) has broken up and released cytotoxins.

How corticosteroids change the picture

Corticosteroids appear to virtually stop the abnormal cellular activity that constitutes the inflammatory reaction. This permits the body's natural resources to clear up the inflamed area and repair the damaged tissue. This interpretation is supported by the fact that when the injurious gelatin solution is injected simultaneously with a corticosteroid — Synalar (fluocinolone acetonide) — the inflammatory pattern simply does not develop.

Fibroblast in high state of activity, much distorted.

Mast cells showing effects of corticosteroid action: cells are normal in size, shape and activity.

In summarizing his study Doctor Dougherty states: "...we also feel this work may explain why one corticosteroid helps a patient more rapidly and effectively than another. If it does, it is because one corticosteroid is the fastest, most effective inhibitor of the series of inflammatory events at the tissue level."

**A New View of Corticosteroid Action in Inflammatory Dermatoses, a film based on this study, is now available from your Syntex representative.*

Visual evidence of how corticosteroids influence the inflammatory reaction

Working with phase-contrast cine-micrography on living animal tissue, Doctors Thomas F. Dougherty and David Berliner of the University of Utah College of Medicine have actually filmed cellular events that occur during the inflammatory reaction. This remarkable study* and additional work by these investigators, as well as by others, have established a new theoretical biologic basis for the antiinflammatory effect of the corticosteroids. (It must be noted that other theories, such as the lysosome or so-called "suicide bag" theory, have been postulated, although it is quite likely that there are more similarities than differences among the various theoretical models.)

The inflammatory wave of destruction

In this investigation an injurious injection of gelatin is used to set off an inflammatory reaction in living mouse tissue. What follows is a wave of destructive cellular activity that comprises the inflammatory response to injury. Mast cells (which contain heparin, serotonin and histamine) take up water, swell and rupture, releasing their contents, which are toxic outside the mast cell wall. These toxins, in turn, cause disintegration of other cells (such as fibroblasts) and the release of additional toxic material. Capillaries, too, take up water and leak unformed blood elements, causing edema. And polymorphonuclears, lymphocytes and perithelial cells invade the inflamed site. As a result of all these changes, the cellular environment reaches a state of turmoil.

How advances in chemical design have achieved greater steroid potency

The chemical modification of corticosteroid molecules from the advent of hydrocortisone to the development of Synalar (fluocinolone acetonide) is a prime example of how biochemists can "design" to increase therapeutic activity and minimize undesirable side actions. Below, for example, we see the important changes that were made in reference to the hydrocortisone molecule to produce fluocinolone acetonide, one of the most active of all topical corticosteroids. As a result, a 0.01% preparation of Synalar (fluocinolone acetonide) has been reported to do the work of a 1% hydrocortisone product containing 100 times more corticosteroid. And it can often do it more effectively.

Hydrocortisone

Fluocinolone Acetonide (Synalar)

- ☐ a double bond between carbons 1 and 2
- ☐ fluorine substitutions at both the 6- α , and the 9- α positions
- ☐ the addition of the acetonide at the 16- α , 17- α positions, thus providing one of the most potent topical corticosteroids available.

How bioassay tests are used to "predict" therapeutic potential

Biologic assays are another tool used by researchers to help establish the relative activity of corticosteroids. To date no single method of assaying corticosteroid activity has emerged as the ideal "yardstick" for predicting therapeutic potential. Taken together, however, these methods have proved useful. When such tests are run on various corticosteroids, a definite order of corticosteroid activity becomes evident. Compounds with the highest order of activity may be expected to merit clinical trial to establish their high therapeutic potential. When assayed by these methods, fluocinolone acetonide (Synalar) emerges as one of the most active topical corticosteroids, milligram for milligram, available for clinical application today.

THE THYMUS INVOLUTION ASSAY¹⁻⁴ is run on adrenalectomized rats. The sizes of the glands are measured, and the degree of involution caused by the steroid is determined as an indication of its potency. In the above photo, the comparative involution of thymus glands achieved with hydrocortisone and Synalar (fluocinolone acetonide) is shown. Untreated controls (A) show normal size. Group B— injected with 1, 2 and 4 mg. of hydrocortisone— show progressively smaller thymuses as does Group C— injected with fluocinolone acetonide— but with only 1/500th the dose of hydrocortisone.

THE ANTIGRANULOMA ASSAY¹⁻⁴ also utilizes adrenalectomized rats. Granulomas are induced by subcutaneous implantation of cotton pellets on either side of the thorax. The degree of granuloma inhibition achieved by a steroid reflects its potency. The above photo shows the inhibition of granuloma formation achieved with hydrocortisone and Synalar (fluocinolone acetonide). Untreated controls (A) show large, red granulomas adhering to the pellets. Group B, receiving hydrocortisone and Group C, receiving fluocinolone acetonide, show little, if any, granuloma formation. Fluocinolone acetonide produced the same effect as hydrocortisone with only 1/500th the dose. This assay, as well as the thymus involution assay, measures systemic rather than topical corticosteroid activity. Nevertheless, results by these methods correlate well with other assays and with the milligram potencies of topical steroids in current clinical use.

Worldwide clinical experience confirms the predictable therapeutic potential of Synalar

It is particularly gratifying that the promise of the advanced chemical design and high order of bioassay activity of Synalar (fluocinolone acetonide) has been confirmed by widespread therapeutic application. Indeed, the impressive clinical response rate of Synalar has been documented in no fewer than 232 papers from 22 countries.

PRESCRIBING INFORMATION

For initiation of therapy: Cream 0.025%, 5 and 15 Gm. tubes, 425 Gm. jars; *for emollient effect:* Ointment 0.025%, 15 Gm. tubes; *for maintenance therapy:* Cream 0.01%, 15 and 45 Gm. tubes, 120 Gm. jars; *for intertriginous or hairy sites:* Solution 0.01%, 20 cc. and 60 cc. plastic squeeze bottles; *for infected inflammatory dermatoses:* Neo-Synalar® Cream (0.025% fluocinolone acetonide, neomycin sulfate, equivalent to 0.35% neomycin base), 5 and 15 Gm. tubes.

CONTRAINDICATIONS: Tuberculous, fungal, and most viral lesions of the skin, (including herpes simplex, vaccinia, and varicella). Not for ophthalmic use. Contraindicated in individuals with a history of hypersensitivity to any of the components. **PRECAUTIONS:** Synalar preparations are virtually nonsensitizing and nonirritating. However, the solution may produce burning or stinging when applied to denuded or fissured areas. In some patients with dry lesions, the solution may increase dryness, scaling or itching. While topical steroids have not been reported to have an adverse effect on pregnancy, the safety of their use on pregnant females has not absolutely been established. Therefore, they should not be used extensively on pregnant patients, in large amounts, or for pro-

Representative Clinical Results with Synalar*

†Expressed by the authors as excellent, very good, good, complete remission of inflammation, etc.

longed periods of time. Prolonged use of any antibiotic may result in overgrowth of nonsusceptible organisms; if this occurs, appropriate therapy should be instituted. When severe local infection or systemic infection exists, the use of systemic antibiotics should be considered, based on susceptibility testing. **SIDE EFFECTS:** Side effects are not ordinarily encountered with topically applied corticosteroids. As with all drugs, however, a few patients may react unfavorably to Synalar under certain conditions. The neomycin in Neo-Synalar Cream rarely produces allergic reactions.

Code of Interprofessional Relations

Minnesota State Bar Association
Minnesota State Medical Association

The Medical Advisory Committee of the Minnesota State Medical Association wishes to call your attention to the Code for Interprofessional Relations of the Minnesota State Medical Association and the Minnesota State Bar Association which was adopted by both Associations in 1960. It is published in the October issue of MINNESOTA MEDICINE in response to many requests received by the committee recently for copies. It has also been published in a recent issue of the BENCH AND BAR OF MINNESOTA, and the committee suggests that you review the entire code with a view to its pertinence and effectiveness. If you have any comments or proposals for amendments please let the committee know.

Donald C. MacKinnon, Chairman

Preamble

Acknowledging that a substantial part of the practice of law and medicine is concerned with the problems of persons who are in need of the combined services of an attorney-at-law (hereinafter called lawyer) and a doctor of medicine (hereinafter called physician), and that the public interest and individual problems in these circumstances are best served by the cooperative efforts of all concerned, we, the members of the Minnesota State Bar Association and the Minnesota State Medical Association, do hereby adopt the following interprofessional code as the standard for proper, ethical conduct for lawyers and physicians.

Interprofessional Relations

Physicians and lawyers, as members of learned professions, have much in common. The state licenses the members of each profession to administer to the needs of and to carry out social responsibility to the public. Each is dedicated to the principle of free choice—freedom of choice in the selection of a physician to safeguard the health of the individual, and freedom of choice in the selection of a lawyer to safeguard an individual's freedoms and rights as a citizen. Each is bound by a code of ethics dedicated to the most worthy objectives inherent in the trust placed in each profession by the community.

The physician has responsibility for the care of his patient, not only in health but also in

disease and injury. He is the adviser and confidant of his patient in matters of health. He must administer to the needs of his patient to the best of his ability and in accordance with the high precepts of the Hippocratic Oath.

The lawyer represents his client as advocate in legal proceedings and as counsellor in business and personal affairs. He is the adviser and confidant of his client in legal matters. He performs his duties as an officer of the court, sworn to support and defend the Constitution of the United States and of the state or states in which he is admitted to practice with high standards of conscience and morality.

The members of each profession are pledged to maintain the confidence and to preserve inviolate the secrets of their patients or clients, as the case may be.

Each profession is obligated by its own stature to respect and honor the calling of the other. Neither the fact nor the appearance of incompetence, corruption, dishonesty or unethical conduct on the part of individual members of either profession can be tolerated. It, therefore, follows that each profession must vigorously support within its own ranks, as well as within the ranks of the other, those ethical concepts which each has found necessary in the public good. But when doing so, the members of each profession must keep in mind that the members of the other profession have been found competent to be such by ap-

Continued

propriate authority, that there are differences in the capacities and characteristics of the practitioners of the other profession, and that while law and medicine may each be termed a science, each is an inexact science and such inexactness is and always will be accentuated by the human limitations of its practitioners.

This interprofessional code constitutes recognition that with the great development in the science and art of both medicine and law, physicians and lawyers are drawn into more and more associations, as the law calls with increasing frequency upon medicine for its scientific knowledge and its evaluation of facts so that the rights of individuals may be appropriately determined before various tribunals.

I. Medico-Legal Aspects Before Trial

The physician becomes involved in the legal process either because he has been engaged for the purpose of diagnosis, care or treatment of some patient whose legal rights are being litigated or because he has been engaged for the purpose of litigation rather than for diagnosis, care or treatment. If he is a physician engaged for the purpose of diagnosis, care or treatment, he will be referred to herein as the attending physician, whether he was the physician who treated the patient during the entire course of his illness or injury or the physician called as a specialist with respect to certain aspects of diagnosis, care or treatment of the patient. If he is a physician engaged for the purpose of litigation, he will be referred to herein as the examining physician.

A. Professional Obligation of Physician to Patient in Regards to Litigation

The attending physician has a duty to assist his patient with respect to any litigation involving the conditions which the physician has treated. This duty arises from his general obligation to assist in the administration of justice and his specific responsibility for the welfare of his patient.

Administration of justice is essential to orderly society. An effective system for settlement of claims involving the physical or mental condition of a person is essential to judicial administration. Disposition of such claims either by trial or in anticipation of trial must be

based on facts relating to (1) liability and (2) damages. The attending physician, by virtue of the confidence reposed in him by his patient has unique knowledge of the physical and mental condition of his patient; the care and treatment required; and the degree of permanent loss, if any, to be anticipated. The issue of damages cannot be fairly resolved without these facts.

It is for the physician to determine the actuality or probability of facts pertaining to his patient's condition. It is for the lawyer to determine when, how and under what circumstances such facts are most appropriately to be presented.

B. Medical Conduct Before Trial

The information obtained by the attending physician in the course of his examination and treatment of a patient and any written report thereof are legally privileged, except that in situations involving the Workmen's Compensation Act an attending physician designated by the Commission or whose services are paid for by the employer may be required to testify as to any information acquired by him in the course of treatment or examination. The information obtained by an examining physician and any written report thereof are not privileged. Nevertheless, an examining physician should not reveal such information or the contents of such report to anyone other than the person employing him without first obtaining the written consent of such person.

Neither the attending physician nor the examining physician should express any opinion to the patient as to the settlement value of any claim for personal injury.

The examining physician, acting for a party adverse to the person he is examining, should, where taking a medical history, attempt to elicit only such facts as are pertinent to his examination; he should not attempt to obtain statements which might constitute admissions with reference to any accident out of which the litigation arises. Such an examining physician should not solicit the findings or the opinions of or consult with the attending physician, nor should he suggest to the person being examined any treatment, comment to such a person on any treatment already received, or divulge to such person any of his medical findings or opinions.

It is not desirable for a lawyer to be present when his client is being examined by an examining physician whether the physician is employed on behalf of his client or on behalf of an adverse party, but there is no reason why the lawyer should not discuss with such physician, either before or after examination, any aspect of the examination that may be pertinent.

C. Legal Conduct Before Trial

A frank discussion of the issues and opinions between the physician on the one hand and the lawyer on the other hand prior to trial is to be encouraged. The lawyer may properly point out the legal foundation for medical evidence and the reasons for it. This does not, however, mean that the physician's testimony must be in accord with these views, for a lawyer by his conscience and his ethics is prohibited from attempting to color or distort the professional opinion of a physician to be called as a medical witness in the trial of a case. Both the lawyer and the physician must share the responsibility for improperly presented or fraudulent medical testimony. Such testimony is unworthy of both professions.

D. Medical Reports

The physician should always stand ready to furnish written reports to lawyers. This statement applies not only to examining physicians but also to attending physicians. The lawyer when requesting a written report from a physician concerning the condition of a patient should make his request in writing and should direct the physician's attention to the particular condition which interests the lawyer.

The lawyer should not expect the attending physician to furnish a report unless the physician has first received a written authorization from the patient permitting the physician to furnish such a report, or the lawyer's letter to the physician contains a signed acknowledgment by the patient of the lawyer's authority to act in his behalf.

A request for a written report should ask for history, diagnosis, treatment, prognosis and medical fees up to the date of the report.

The physician has an obligation to keep adequate records which may be used to supply to

a patient's lawyer all information regarding the patient-client's medical history, and to retain control of x-rays.

Requests for medical reports should be honored promptly, as undue delays in providing medical reports or bills bearing on a patient's legal rights may prejudice the patient's rights.

If a physician is unable to state a complete medical evaluation and prognosis at the time it is required, he should so notify the lawyer and suggest to him that he request a further medical report at a later time. In such instances a preliminary report and medical bill, clearly designated as such, will often serve the patient's needs adequately.

E. The Interprofessional Conference

Personal conferences between the lawyer and each physician, whether he be an attending physician or an examining physician, are always proper and generally should be regarded as professionally obligatory.

Conferences should be scheduled at mutually agreeable times and under circumstances so that they may proceed without interruption.

Several conferences may be necessary. An initial conference long prior to trial and in some cases even prior to the commencement of a lawsuit is often desired by the lawyer so that he may be early apprised of the medical aspects of the claim, knowledge of which is, of course, essential to an evaluation of the claim. Interim conferences to discuss the patient's medical progress are often also necessary. If the physician is to be a witness, a final conference should be held as shortly as possible before the physician is to give testimony. At this conference the lawyer should explain the legal aspects of the case and the facts he expects to develop; and fully and with complete candor the physician should explain the medical aspects of the case. If a hypothetical question is to be asked, the lawyer should clearly outline it at the conference. The physician should review with the lawyer at the conference all his notes, records, memoranda and x-rays even though he does not intend to use them in his direct examination because they may be used in cross-examination. Before the conference concludes the physician should volunteer any pertinent medical fact not previously discussed.

Continued

F. Arrangements for Medical Testimony in Court

The lawyer should make arrangements with the physician who is to be a witness for the physician's appearance at a particular time and place and for the physician's testimony to be given as close to the specified time as possible. It is the obligation of the physician to be present at the specified time. The lawyer should give the physician as much advance notice of the specified time as is reasonably possible, but the physician must realize that the lawyer cannot control the court calendar and that unanticipated dispositions of preceding cases frequently prevent the lawyer from giving as much advance notice as might be desired. When a case is settled, the lawyer should promptly notify all physicians involved. Prompt notice is particularly important when a case is settled after a time for the physician's appearance in court has been set.

G. Subpoenas to Secure Medical Testimony

The lawyer should make every effort to arrange his client's medical evidence without the use of subpoena. In the event medical evidence cannot be obtained by arrangement, the lawyer may subpoena the physician. The physician must appear at the time requested and should not take offense at being subpoenaed. In the event a lawyer finds it necessary to subpoena a physician, the lawyer should notify the physician in ample time, preferably in advance of service of the subpoena, of his intention and insert in the subpoena a time for appearance as nearly as possible acceptable to the physician. A lawyer who subpoenas a physician should not expect the physician to bring with him his notes, records, memoranda and x-rays unless the physician has been served with a subpoena duces tecum.

Even though all physicians are experts in the eyes of the law, a physician can be compelled by subpoena to appear and testify upon tender to him of the statutory witness fees payable to any lay person who is subpoenaed. If a physician who appears in answer to a subpoena is examined with respect to any subject upon which he is an expert, the judge may at the conclusion of his testimony allow him a reasonable expert witness fee.

II. The Medical Witness at Trial

A. Appearance of Medical Witness

The proper, fair and impartial presentation of medical testimony is the joint responsibility of the physician acting as a medical witness and both examining lawyers.

The persons who are to hear and interpret the medical testimony, be it a jury, judge, or other presiding official, must necessarily observe and consider the appearance of the witness and presentation of the testimony. A medical witness should maintain a professional attitude in his appearance and should present his testimony in language that a layman can understand.

Our system of justice assumes that medical witnesses as well as other witnesses are impartial as to the facts within their knowledge. They are not and should not be advocates. A dogmatic, uncompromising, and argumentative attitude assumed by a witness instead of a firm but professional attitude based on honest convictions established on scientific principles will work to the detriment of the witness and as a result will work to the detriment of the patient on whose behalf he is testifying.

A lawyer should not engage in the abuse of any witness, including a physician, whether the witness be called by one side or the other. The established rules of evidence give ample opportunity for testing the competence and credibility of all witnesses, including a physician, making abusive examination on the part of a lawyer unnecessary and unjustifiable.

The physician should realize that it is the privilege and obligation of the lawyer for the opposing side to conduct his cross-examination with vigor in an effort to explore the foundations of medical opinion and to expose weakness which may appear in either the basis or content of such opinions. The physician should not be upset or assume an antagonistic attitude toward such cross-examination, providing the examining lawyer conducts it in a professional and gentlemanly manner. The physician must realize that such cross-examination is most probably based upon contrary medical interpretation of the objective facts known to all. A refusal to tolerate or to recognize a contrary view will not be in the best interests of the ad-

ministration of justice.

B. Medical Testimony

A physician should bring with him to court all his records with respect to the patient about whom he is testifying and may request that the hospital records with respect to such patient also be present in court. A lawyer should not counsel against the production of such records. When preparing to testify or when testifying a physician may examine such records to refresh his recollection. Once he has used them for such purpose, the lawyer for the opposing party may examine them too.

The qualification of a medical witness involves an inquiry into his medical education, post-graduate training and research and his membership in various medical organizations. The physician should be prepared to give a resumé of these professional qualifications without hesitation but without undue elaboration.

In the giving of testimony, the physician under no circumstances should permit any bias, prejudice, favoritism or personal interest to influence or affect his testimony. If the physician is asked a question to which he does not know the answer, he should so state and make no attempt to speculate or guess or theorize or give answers not responsive to the question propounded. A physician should not hesitate to express his opinions which are based upon a reasonable medical certainty. The medical witness is not required to exclude all doubts from his mind but may render his testimony as an opinion couched in expressions which fall short of an absolute conviction of accuracy. Simply because someone else might not agree with his opinions should not cause the physician to hesitate in expressing them. He must also remember that it is only fair that a contrary interpretation of the medical facts may exist and may be admitted. The physician must state his opinion if he has one. However, if he feels he is not qualified to give one, he should so state, and if he has no opinion he cannot be compelled to give one.

Trials are conducted according to rules of evidence and a physician may find that frequently during the presenting of his testimony there will be objections. These objections by the lawyers are merely a request to the court to

pass upon the materiality, the relevancy, or the competence of the testimony being offered. The court will rule according to the rules of evidence and the decision will be made as to whether the testimony should be considered along with other evidence in the case. The physician should not feel frustrated by these frequent interruptions since they are important and essential to protect the relative rights of the clients who are litigants.

It is frequently necessary to use hypothetical questions in eliciting testimony from medical witnesses. Such questions can be lengthy, troublesome and confusing if not properly prepared and presented. It is the lawyer's obligation to present such questions so as to be free from ambiguities and to eliminate any possible misunderstandings. The medical witness in attempting to answer the question, must, of course, be sure that he understands all of its elements and that they are sufficient and complete enough so that he can properly predicate his opinion thereon.

C. Ethical Limits of Medical Testimony

It is a rare occasion when intentional false or improper medical testimony is given in the trial of a case. However, it has occurred. Similarly, there are occasions when lawyers exceed the limits of propriety and attempt to introduce improper medical testimony or attempt to influence the testimony of the medical witness.

Each of the members of both professions has a duty to satisfy himself as a matter of conscience and professional judgment that the person doing so has exceeded the limits of ethical medical testimony or ethical handling of medical witnesses and once doing so has the obligation of reporting such activity to the appropriate organization within the profession which is set up to handle such matters.

The reputation of a professional person is his most precious and valuable asset. Therefore, the reporting of such improprieties against a member of one's own profession or against the member of another profession is a matter of great seriousness and calls for a high degree of discretion. It must be remembered that in an area such as medical testimony, there is a large degree of variance in opinions and in most cases these opinions are based

Continued

upon sound medical authority. The possibility of unintentional misstatements or representations also must be considered. Therefore, before any action is taken of any kind, the person doing so must be absolutely certain in his own mind and conscience that such action is warranted.

Conversely, it is just as serious to abstain from reporting such misconduct as it is to make a groundless charge. Therefore, when a member of either profession becomes convinced that such misconduct has occurred, it is his duty to report it.

III. Compensation of Medical Expert

A. Medical Fees

1. Contingent Fees

It is improper for the lawyer and the physician, whether he be an attending physician or an examining physician, to enter into any arrangement making the payment of medical fees, or the amount thereof, contingent upon the outcome of the litigation. Fixed fees should be established prior to the examination or court appearance.

2. Attending Physician

The expense of care and treatment of the patient is the obligation of the patient, irrespective of the litigation or the outcome thereof. The expense, if any, for preparation of medical reports for use by the patient's lawyer is the obligation of the patient. The expense of court appearance or preparation therefor is the obligation of the patient. The lawyer for the patient is under no legal obligation to pay such fees.

It is improper for the attending physician to insist, as a condition precedent to his testimony, that the lawyer for the patient guarantee payment of an unpaid bill for medical services, or bills for services to be incurred for the court appearance.

3. Examining Physician

The expense of an examination and report by an examining physician, as well as x-ray expense and similar costs necessary for a complete examination, are obligations in the first

instance of the lawyer requesting the same. Similarly, the expense of court appearance is an obligation in the first instance of the lawyer requesting the same. This fact does not relieve the client of his ultimate liability to pay the examining physician or reimburse his lawyer.

It is proper and desirable practice that whenever a lawyer refers a client to a physician for examination he should do so in writing, stating the terms of the reference. If the lawyer disclaims liability for the fee or if the physician doubts the lawyer's credit, the physician may be justified in withholding his report until the fee is paid or in declining to testify until mutually satisfactory financial arrangements have been made.

Payment of the examining physician's fees should be made promptly upon completion of his services. Delay in the final disposition, such as appellate procedure, is not sufficient reason for a lawyer to delay payment.

4. Court Appearances

The lawyer and his client should realize that a physician's fee for a court appearance is based upon many factors among which are not only actual time away from office but also stand-by time—i.e., the hours for which the physician has not been able to arrange a normal schedule of appointments either because he does not know exactly when he must appear in court or because he does not know exactly when he will return from court. They should also recognize that a physician is entitled to charge a fee for a court appearance if a case is settled while he is in the courtroom or if he has incurred stand-by time even though in either case he has not testified.

B. Professional Obligations of Attorney to Protect Physician for Fees on Services Rendered

In the event of recovery, the lawyer has an obligation to use all reasonable measures to assure payment by the client of the statement for services of the attending physicians, not only for the court appearance but also for services rendered. Whenever possible, unpaid statements should be satisfied as part of the process of distributing funds recovered in the litigation. A lawyer unable to make arrange-

ments for satisfaction of unpaid medical bills should promptly notify the physician of such facts.

Interprofessional Understanding

This code of interprofessional relations has been designed to promote better understanding between physicians and lawyers. If it is studied carefully and followed diligently by members

of both professions, it should go far to eliminate the frictions that have arisen and to enhance the areas of understanding. Improvement of the relationships between the two professions will enable the two professions to progress together in their service to humanity and its individual ills, whether of body, of mind, or to rights guaranteed under our system of justice.

Problems of Multiple-Handicapped Meeting

Plans are underway for a series of lecture and discussion meetings for Minnesota physicians on the problems of multiple-handicapped patients and how the creation of special diagnostic, evaluation and treatment centers throughout the state could aid these children, as well as the physicians whose patients they are.

Meetings are being scheduled for November 2 and 3 in Rochester, the Twin Cities and St. Cloud.

Speaker will be Dr. Richard Koch, chief of pediatrics at Children's Hospital, Los Angeles, Calif.; director of the Child Development Clinic at the hospital, and associate professor of pediatrics at the University of Southern California's School of Medicine, Los Angeles.

"Dr. Koch is widely known throughout the country as a pioneer in the establishment of these special Child Development Centers to help the child with the multiple handicap," said John Broady, St. Paul, executive director of the Minnesota Mental Retardation Planning Council.

Working with the Planning Council in sponsoring the meetings is the University of Minnesota's Department of Child Psychiatry. Other co-operating groups include: the Minnesota state department of education, division of special education; state department of health; state department of public welfare and its division of rehabilitation, child welfare and services to the blind; the Minnesota Association for Retarded Children; United Cerebral Palsy Association; Minnesota Society for Crippled Children and Adults, and the Easter Seal Society.

*O hour of all hours, most bless'd upon earth,
 Blessed hour of our dinners!
 We may live without poetry, music, and art;
 We may live without conscience and live without heart;
 We may live without friends; we may live without books,
 But civilized man cannot live without cooks.
 He may live without books—what is knowledge but grieving?
 He may live without hope—what is hope but deceiving?
 He may live without love—what is passion but pining?
 But where is the man that can live without dining.*

—Owen Meredith

Dr. Albert Einstein neatly summed up worry when asked if he ever worried about the future. "Why should I?" he answered calmly. "It gets here fast enough anyway."—Argosy.

The Arthritis Foundation salutes the thousands of dedicated physicians who volunteer their services in the nation's fight against crippling arthritis.

The Arthritis Foundation is the sole national voluntary health agency committed to conquering the rheumatic diseases. It provides the means for dynamic partnership between physicians and laymen to marshal leadership and resources toward the solution of this major national health problem.

The Arthritis Foundation looks forward to rapid growth with increasing opportunity for physicians to participate in the arthritis movement. For further information about The Arthritis Foundation and its programs write to the Foundation chapter in your community or to the Medical Department, Box 2525, New York, N.Y. 10001.

Minnesota Medicine at a Glance

Paradox of Brucellosis—*MacDonald et al.*

Page 1469.

The authors discuss the current brucellosis scene. The classification they find most useful divides cases into bacteremic, serologic, localized and mixed types. The current antibiotic regimen of reference is a combination of tetracyclines and streptomycin. Emphasis is placed on surgical drainage of suppurative brucellar infections.

Farm Accidents—*Muckala*

Page 1477.

We in Minnesota have no functioning Agricultural Extension Safety Division concerned with safety education, promotion and design. It is essential for a major agricultural state and a major university medical center to have a professional group, or institute, to concern itself with the epidemiological aspects of rural health and farm safety. It can also function as a source of information and education for the professional portions of our rural communities who are directly concerned in health promotion and preventive medicine.

Polymyalgia Rheumatica—*Nuessle et al.*

Page 1483.

A cluster of findings, including muscular pain, high sedimentation rate, ocular symptoms, and occasionally giant cell arteritis of temporal vessels is described in seven cases. The syndrome, entitled polymyalgia rheumatica, appears in old women and is considerably relieved by steroid therapy.

Bacteremia and Candida Septicemia—*Salter and Zinneman*

Page 1489.

The authors have reviewed 185 cases of bacteremia and fungemia seen at the Minneapolis Veterans Administration Hospital in a four-year period between 1962 and 1965. They found a high incidence of coagulase positive staphylococci and *Escherichia coli*. The most common gram-negative organisms were *Proctus* and *Klebsiella enterobacter*.

In the first year of the study *Candida* was present in 4.6 per cent of the total number of positive cultures, but in the last year of the study was present in 11.9 per cent. The urinary tract was the most common source of non-fatal bacteremias, followed by respiratory tract. But in fatal bacteremias this was reversed. The most important factor associated with the positive blood culture was the presence of other disease, particularly neoplastic disease and especially of the hematopoietic system. Diabetes mellitus, gastrointestinal, biliary tract disease, chronic lung disease and genitourinary tract disease were underlying conditions. The intravenous pyelogram polyethylene catheter is a frequent portal of entry. Shock during the course of bacteremia was associated with a mortality of almost 60 per cent.

Dilantin® (diphenylhydantoin)

PARKE-DAVIS

In untold thousands of epileptic patients... Dilantin has been, and continues to be, the bedrock of therapy.

DILANTIN is useful in the treatment of grand mal epilepsy and certain other convulsive states. Its use will prevent or greatly reduce the incidence and severity of convulsive seizures in a substantial percentage of epileptic patients, without the hypnotic and narcotizing effects of many anti-convulsant drugs.

PRECAUTIONS: Periodic examination of the blood is advisable. Nystagmus in combination with diplopia and ataxia indicates dosage should be reduced. The possibility of toxic effects during pregnancy has not been explored. **ADVERSE**

REACTIONS: Allergic phenomena such as polyarthropathy, fever, skin eruptions, and acute generalized morbilliform eruptions with or without fever. Rarely, dermatitis goes on to exfoliation with hepatitis, and further dosage is contraindicated. Gingival hypertrophy, hirsutism, and excessive motor activity are occasionally encountered. During initial treatment, side effects may include gastric distress, nausea, weight loss, nervousness, sleeplessness, feeling of unsteadiness. Macrocytosis, megaloblastic anemia, leukopenia, granulocytopenia, thrombocytopenia, pancytopenia, agranulocytosis, and aplastic anemia have been reported. Nystagmus, lymphadenopathy, lupus erythematosus, erythema multiforme (Stevens-Johnson syndrome), and a syndrome resembling infectious mononucleosis with jaundice have occurred. DILANTIN is supplied in several forms including Kapseals® containing 0.1 Gm. and 0.03 Gm. diphenylhydantoin sodium.

Parke, Davis & Company, Detroit, Michigan 48232

The color combinations of the banded capsules are Parke-Davis trademarks. The orange-banded white capsule identifies Parke-Davis 0.1 Gm. diphenylhydantoin sodium; the pink-banded white capsule 0.03 Gm. diphenylhydantoin sodium.

LACTINEX[®]

TABLETS & GRANULES

■ to help restore and stabilize
the intestinal flora

■ for fever blisters and canker
sores of herpetic origin

LACTINEX contains both *Lactobacillus acidophilus* and *L. bulgaricus* in a standardized viable culture, with the naturally occurring metabolic products produced by these organisms.

First introduced to help restore the flora of the intestinal tract in infants and adults,^{1, 2, 3, 4} LACTINEX has also been shown to be useful in the treatment of fever blisters and canker sores of herpetic origin.^{5, 6, 7, 8}

No untoward side effects have been reported to date.

Literature on indications and dosage available on request.

ACID & AIR

DUAL PROBLEM IN PEPTIC ULCER

Relief of hyperacidity is still a primary goal in the treatment of peptic ulcer. And antacids are the most widely used means of achieving this relief. But antacids alone cannot influence the distention and bloating which so often add to ulcer distress.

THIS IS WHY MYLANTA® PROVIDES:

the two most widely used antacids—magnesium and aluminum hydroxides—to help secure rapid acid neutralization with little chance of laxation or constipation;

PLUS

the defoaming action of simethicone—to help relieve the painful gas symptoms which often accompany peptic ulcer.

Mylanta®

antacid therapy plus an added benefit

nonfatiguing flavor/smooth pleasant texture; both assure patient cooperation during long-term therapy.

GENERAL INFORMATION

Authors

Send manuscripts for consideration to MINNESOTA MEDICINE, 375 Jackson Street, St. Paul, Minnesota 55101.

Bibliographic references should conform to the method used by Index Medicus. A maximum of 12 references will be published, but all references will appear in the reprints.

Illustrations, photographs, tables, graphs, and pen and ink drawings are encouraged. If the drawings are not acceptable they will be commercially reproduced and the author will be billed.

All manuscripts will be edited and stylized to conform to the format used in MINNESOTA MEDICINE. The content of the manuscript will not be altered.

Minnesota Medicine Award

An award will be given at the annual meeting to the author of the most meritorious manuscript for the preceding year.

Picture of painful myositis

treated with Parafon Forte® TABLETS

Paraflex® (chlorzoxazone)* 250 mg.
Tylenol® (acetaminophen) 300 mg.

**Parafon Forte helps to relieve pain,
restore mobility . . . stop pain-spasm feedback**

Here is why. PARAFON FORTE provides:

a nonsalicylate analgesic equal to aspirin for the relief of pain,^{1,2} yet unlikely to produce the irritation to the gastric mucosa so often associated with salicylate therapy³

and a skeletal muscle relaxant shown to have up to a 6-hour span of action,⁴⁻⁶ and to retain effectiveness even on continued administration,⁵⁻⁷ but which does not have the central effects of tranquilizing compounds.

Prescribe PARAFON FORTE for lasting spasmolysis and analgesia in sprains, strains, myalgias, low back pain, bursitis and other musculoskeletal disorders. Your patients will appreciate the restored comfort and lasting freedom of movement it usually provides.

Cautions and side effects: Use with caution in patients with known drug sensitivity. If a hypersensitivity reaction or symptoms suggestive of liver dysfunction are observed, the drug should be stopped. Occasionally, drowsiness, dizziness, light headedness, malaise, overstimulation or gastrointestinal disturbances may be noted; rarely gastrointestinal bleeding, allergic skin rashes, petechiae, ecchymoses, angioneurotic edema or anaphylactic reactions may have been drug associated. While *Paraflex* (chlorzoxazone) has been suspected as being the cause of hepatic toxicity in approximately eighteen patients, it was not possible to state that the dysfunction was or was not drug induced. **Dosage:** Two tablets q.i.d. **Supplied** Scored, light green tablets, imprinted "McNEIL"—bottles of 100

President's Letter

ALL THE PHYSICIANS of Minnesota, especially the General Practitioners or Family Physicians, have lost, at least temporarily, a stalwart champion in the University of Minnesota Medical School. I do not mean to imply that he is the only one there who has the great interest of this group in mind, but, in my humble opinion, he is oriented to both "patient care" and General Practice. Such a man is Dr. Richard M. Magraw. He has taken sabbatical leave to serve as Consultant to the Surgeon General, and especially to the Bureau of Health Services.

Dr. Magraw has labored for years with his Comprehensive Clinics at the University Medical Center. He sprang into national prominence with the publication of his very excellent book, "Ferment in Medicine," which came out this past year and should be a MUST for every physician to STUDY. I read fairly rapidly, but I couldn't go through this book in a hurry and am in the process of restudying it now.

It is my hope, and I think I can safely say that this hope is shared by the great majority of physicians in the state, that he could be replaced by someone with the same dedication to the principles for which he stands. It would seem reasonable to assume that the "talked about" new department of General Practice, or whatever it is to be called, could somehow be developed from these Comprehensive Clinics. Its head must be a strong individual, capable of withstanding much storm and strife, because he will be shot at from all directions, I would predict, and it will be very difficult for him to make this department into a "going" concern. Now is the time when Dr.

Magraw should be really getting into stride here, because he has the background and intestinal fortitude to develop such a department.

I say this with as much kindness as I can, and without meaning to be cynical. Years ago the entire Medical School faculty was "patient care"-oriented, because research was in its infancy. As time has passed, it is very understandable that it should swing more and more into the "research"-oriented orbit, along with the tremendous burgeoning of our total scientific effort. During this process, however, the "patient care" attitude has suffered and become somewhat of a stepchild of academic medicine.

It is obvious that both viewpoints are required; the problem is one of emphasis. We are "off trajectory," as it were, and any re-orientation must necessarily come through the combined efforts of those supporting both points of view. Such reemphasis *must be accomplished* by the cooperation of the entire faculty, as well as the Metropolitan Community in which it is situated. I would guess that the great majority of the faculty is more "research"-oriented than "patient care"-oriented. Of necessity, research cannot be neglected, but more emphasis must be placed on teaching the students to be practitioners of medicine. It should certainly be possible to combine the two, as most research should be aimed at improvement of health, rather than being "pure" research, which so much of it seems to be at the present time.

If any of the faculty wishes to dispute these statements, I would be pleased to see a "Letter

Diverticular Disease of the Colon

GHISLAIN J. DEVROEDE, M.D.*
RICHARD J. REITEMEIER, M.D.**
Rochester, Minnesota

IN THE LAST few years, investigators in England and Sweden have clarified the concepts of etiology and pathophysiology of diverticular disease. The function of the normal sigmoid colon has been better defined and contrasted to an altered function in diverticular disease. On the basis of these studies, a relationship between the irritable colon syndrome and diverticular disease can now be suggested.

Etiology and Pathogenesis

Understanding of the development of diverticula has been obscure until recent years. Weakness of the muscle layer of the colon has been thought responsible, as has increased intraluminal pressure. Several objective studies have now shed some light on the pathogenesis of diverticula.

Alteration of Intraluminal† Pressure

Pressure in the rectosigmoid can now be recorded by placement, through a proctoscope, of fluid-filled tubes connected to a manometer, and this relatively new technique has provided considerable new data.

Quantitative Measurement of the Intraluminal Pressure

The intraluminal pressure and the degree of muscle activity in the sigmoid colon have been studied in normal volunteers and compared with those in patients who had evidence of diverticular disease of the colon. This was done by Arfwidsson in Sweden¹ and Truelove and his school in England.²⁻⁸

In measurements at rest, Arfwidsson¹ found about a five-fold increase in total muscle activity in patients with diverticular disease as compared with healthy subjects. In addition, there were more waves reflecting high pressure in the patients with diverticular disease; and complex waves were present that did not occur in normals. On the other hand, Painter and True-

*Mayo Graduate School of Medicine (University of Minnesota), Rochester: Resident in Colon and Rectal Surgery.

**Mayo Clinic and Mayo Foundation: Section of Medicine.

†See Test Your Word Score Page 1659.

love,² using the same technique but a different method of analysis, did not find a statistically significant difference between these groups.

In postprandial measurements, both Arfwidsson's and Truelove's groups observed that after a meal the intraluminal pressure in the sigmoid was increased in both normals and patients with diverticular disease, but to a much more marked degree in the latter.^{1,8}

The effect of various drugs has been studied. Neostigmine (Prostigmin) was found by both groups^{1,4,6} to increase markedly the intraluminal pressure in both the normal and the diseased colon, but again to a much more marked degree in the diseased state. Morphine was found by Painter and Truelove³ to have the same effect. Meperidine (Demerol), on the other hand, did not have this action; it depressed the muscular activity of the colon.⁵ In one study, analysis of patients hospitalized for diverticular disease disclosed three cases in which perforation of the bowel was attributed to the administration of morphine.⁶ These studies are the basis for the recent recommendation to avoid the use of morphine in diverticular disease of the colon and to control pain when necessary with meperidine.

Propantheline (Pro-Banthine) inhibits the motility of the colon and can prevent morphine-induced contraction when the drugs are given simultaneously.⁵

Effect of Increased Intraluminal Pressure: Genesis of Diverticula

The studies just referred to demonstrate that the intraluminal pressure of the colon in diverticular disease can be quite high. How can this lead to the development of diverticula?

The musculature of the human sigmoid colon has certain peculiarities which may explain how a high intraluminal pressure can be quite localized. The muscle wall consists of two layers. Three longitudinal taeniae constitute the outer layer; one is located at the mesenteric border and two are at the antimesenteric border. The latter come quite close to each other in the region of the sigmoid. The inner circular muscle is fasciculated—that is, grouped in bundles. This lack of continuity helps explain the genesis of diverticula. Both muscle layers are attached to each other at their junctional surface, so that contraction of the taeniae produces crowd-

ing of the circular bundles, shortening of the sigmoid, and, more important, partial segmentation of the sigmoid. Two localized contractions of the circular bundles can now occlude the lumen completely at each end of a segment of sigmoid; and if the intervening circular muscle of the segment contracts, a very high pressure is generated.

Pressures of considerable magnitude were often found to be localized.^{2,7} Pressure-recording devices were placed at different levels in the rectosigmoid, and the motility patterns registered were without relation to each other in time or in intensity. However, only those leads related to diverticula recorded increased pressures. When cineradiography was combined with pressure recording, it was seen that the colon-bearing diverticula functioned as a series of separate segments and that distention of the diverticula occurred when the related segments contracted.⁷

It has been argued that the increased intraluminal pressure is the consequence and not the cause of diverticular disease. However, Arfwidsson has described several patients with a prediverticular condition in which the intraluminal pressure is increased but without associated diverticula.

What Produces an Abnormal Motility Pattern?

Because of a marked predominance of sympathetic activity, the colon is normally fairly relaxed.⁹ There is evidence in some subjects that stress alters this condition;¹⁰ pain, induced hypoglycemia, and physiologic trauma have been shown to increase markedly the motility of the sigmoid.

A study of patients with the irritable colon syndrome discloses differences from the normal relaxed state of the colon. Such patients can be divided into two groups:¹¹ those who have a "spastic" colon manifested by pain that occurs mainly along the course of the left colon, and more rarely, those having painless diarrhea. Reaction to stress in both groups of individuals is of greater intensity and duration than in the normal.¹⁰ Pressures recorded in the same manner as described above showed normal patterns in the absence of symptoms, a decrease in activity in the diarrhea group when they had symptoms, and an increase in the group having pain.¹²⁻¹⁴ In the last-named,

segmental contraction like that seen in patients with diverticular disease was seen by cinefluoroscopy and could be abolished by propantheline.¹¹ In both forms there is an abnormal increase in motility in response to neostigmine (Prostigmin)^{11,12} and meals.¹⁵ No prospective or retrospective study is available as yet to link the irritable colon syndrome—a presumed psychosomatic condition—to diverticular disease—an organic disease. However, from what has just been described, the analogy is striking and the bulk of evidence now points to a possible relationship. Occasionally, it is possible to follow the development of diverticula superimposed on a spastic colon.¹⁶

Influence of Diet

The chronic feeding of rats with a low-residue diet produced diverticula; this did not occur in a group fed a normal diet.¹⁷ No diverticula are present in Africans living tribally in Africa.^{7,18} Their diet is high in bulk. Among their American cousins there has been a steady increase in diverticular disease in the last 50 years coinciding with a reduction of the residue in their diet. Virtual absence of diverticulosis has been reported in Korea, where the diet is composed of a large proportion of high-residue elements.¹⁹

Such evidence allows a basis for revision of our traditional concepts of diet in diverticular disease. The use of the low-residue diet in the irritable colon syndrome and for patients with diverticular disease would not appear justified on the basis of the above evidence. It would seem more reasonable to avoid obliteration of the sigmoid lumen when possible, and a diet high in residue may afford some protection in this regard.

Although in most cases of diverticular disease of the colon, the sigmoid is involved and progression occurs orad from there, some diverticula can occasionally be demonstrated in the transverse colon or the right colon without involvement of the left side.^{1,7,20,21} In the sigmoid, the lumen normally is smaller and the muscle thicker than elsewhere in the colon, and this may explain the frequency of its involvement with diverticula.^{1,22,23}

Pathology

The Diverticulum

Acquired diverticula of the colon are usually

located between the taeniae of the mesenteric border and those of the antimesenteric border. In the advanced stage of the disease, a few smaller ones may appear between the latter.^{16,24} Dogs have no taeniae but a continuous longitudinal sheet, and diverticula in these animals never develop. Perhaps for the same reason the human rectum is free of this disease.

Microscopically, the diverticulum is usually formed by a mucosal outpouching along the blood vessel pathways piercing the circular muscle.

As noted previously, prediverticula have been demonstrated by Arfwidsson.¹ He studied two patients who had symptoms of pain in the left lower quadrant, the typical saw-tooth pattern of the sigmoid on x-ray study, and a motility recording like that described above. Both patients underwent resection of the sigmoid, and in each the ends of the sigmoid were tied off after the specimen had first been filled with formalin to a pressure of 60 cm. of water. After two days in a formalin bath, the specimens were examined. Tiny diverticular precursors were found which were described as outpouchings of the submucosa along the vessel pathways. For these the term incomplete or intramural diverticula has been coined.²⁵

Some authors have called attention to the fact that to have symptoms it is not necessary to have inflammation of the diverticula^{1,16,26-28} or to have a mass palpable clinically or at surgery. In one series²⁷ 30% of specimens from patients operated on for diverticulitis did not have any sign of inflammation. Arfwidsson¹ found no inflammation in eight of 29 specimens. Morison²⁷ in England and Fleishner and associates¹⁶ from Harvard are in agreement with these findings.

It is postulated that once the mucosa has been damaged, infection can occur and extend toward the pericolic fat and the peritoneum. The mucosa adjacent to the diverticula is rarely affected.¹

Chronic infection of the mucosa of the diverticulum results in the formation of granulation tissue²⁷ and can cause the ulceration of an arteriole²⁹ with resultant bleeding.

Colon Musculature

The musculature of the colon may be remarkably thickened in diverticular disease.

Statistical analysis shows true hypertrophy rather than hyperplasia,¹ but this has recently been challenged.³⁰ Pleating of the wall also occurs,^{1,16,27,28} and microscopic examination reveals that it involves not only the mucosa along the taeniae but also the whole wall in between them. Stripping the taeniae¹⁶ permits stretching of the specimen beyond its normal size, and this shows the importance of the taeniae in the genesis of the pleating. Cineradiography⁶ has shown that despite the increased thickness of the muscle, the neck of the diverticulum was not shut off during contraction.

Colon Fat

Increase in fat may be more apparent than real and represent the crowding of the bowel by spasm.^{27,31}

Symptomatology

Although classically diverticulosis has been held as asymptomatic, the noninflammatory stage of the disease may in fact be related to some of the symptoms previously attributed to diverticulitis.²² Pain and symptoms from intermittent partial obstruction do not necessarily indicate infection, nor does a tender mass in the left lower quadrant. Only fever and peritoneal irritation can be securely related to inflammation together with leukocytosis and elevation of the erythrocyte sedimentation rate.

Proctoscopic Examination

In diverticulosis the bowel may be fixed and angulated, and occasional diverticula may be seen. These can be inverted and they may simulate a polypoid lesion. To this picture edema and erythema of the mucosa may be added in diverticulitis.

Roentgenologic Examination of the Colon

Barium at times flows in with difficulty both in irritable colon syndrome¹¹ and in diverticular disease. A saw-tooth pattern on the x-ray film is typical of both diseases;^{1,22} the lumen of the sigmoid is smaller than usual and is segmented by deep indentations of the colonic wall.^{7,11,16} When present, diverticula are located at the top of the haustra between these contraction rings. Postevacuation films often

show retention of barium in diverticula or segmented pockets of colon.

Exclusion of carcinoma on a roentgenologic basis can be difficult. As a rule, diverticular disease involves a longer segment with normal mucosa and without short abrupt edges; fluoroscopy may demonstrate spasm²¹ in diverticular disease.

Fistulas or communication with an abscess can sometimes be demonstrated on postevacuation films after an acute episode.²¹

Finally, if barium enema is necessary in acute diverticulitis, caution should be used to avoid perforation.

Treatment

Medical Treatment

Two main points have to be emphasized. One is the suggested avoidance of morphine and its replacement by meperidine for control of severe pain. The other is the use of a high-residue diet and bulk-forming laxatives in both irritable colon syndrome and diverticular disease.

In cases of acute diverticulitis, bed rest, sedation, propantheline, antibiotics by mouth or parenterally, and local heat should be instituted.

Surgical Treatment

Indications.—Only 5% of patients who have diverticular disease undergo surgery. For many years surgical treatment was limited to the treatment of the complications: perforation, fistula, obstruction, and uncontrolled bleeding. In addition, acute diverticulitis associated with high mortality has been reported to occur in patients who have had no previous episodes,³² and in these patients resection was eventually undertaken. Arfwidsson has recommended that the association of high intraluminal pressure, typical x-ray pattern, and intractable symptoms be regarded as surgical indication. In some instances, the impossibility of excluding carcinoma is also a surgical indication.

Surgical Techniques

A trend has developed to replace the classic three-stage procedure (colostomy-resection-closure of colostomy) by the one-stage resec-

tion without colostomy.^{31,33-35} It was shown that the one-stage operation carries less morbidity and the same operative mortality.³⁶ One randomized study, grouping all perforated lesions of the colon, is available and shows a higher mortality and morbidity in the multiple-stage group.³⁷ Surgical resection is followed by virtual absence of recurrence.^{31,33,35}

Sigmoid myotomy has been devised by one author to attack the problem at a more physiological level.³⁸ An incision of six inches or more, carried from the peritoneal surface to the level of normal colonic mucosa,³⁹ is made along the antimesenteric taeniae, cutting all circular muscle. Time will tell the usefulness of such procedures.

Summary

Thanks to recent studies, we now understand more of diverticular disease of the colon and have a meaningful concept of its cause, pathogenesis, and physiology. Our recommendations can now be more rational. Of importance is the avoidance of morphine, its replacement by meperidine and propantheline, and the usefulness of a high-residue diet.

Diverticulosis, previously thought harmless, has been found in some cases to be associated with symptoms.

The one-stage resection is becoming the procedure of choice for surgical treatment.

Man is a gregarious animal, and apparently the mischievous microbes he exhales fight and neutralize each other. They go out and devour each other, and Man walks off unharmed. If this is not scientifically correct, it ought to be.

—Winston Churchill

Count that day won when, turning on its axis, this earth imposes no additional taxes.

—Franklin Adams

Acupuncture*

An Ancient Chinese Practice

"That a needle stuck into one's foot should improve the functioning of one's liver is obviously incredible. It can't be believed because, in terms of currently accepted physiological theory 'it makes no sense.' Within our system of explanation there is no reason why the needle-prick should be followed by an improvement of liver function. Therefore, we say it can't happen.

"The only trouble with this argument is that, as a matter of empirical fact, it does happen. Inserted at precisely the right point, the needle in the foot regularly affects the function of the liver."**

Just where is that "right point"? On a diagram of the human figure it is labeled Liv 2 and is situated on top of the right foot between the first and second toes. How can it be precisely determined? The acupuncturist expertly glides a sensitive finger along the liver meridian (circuit) which, in a case of suspected liver disease, responds with a tender pulsation at the exact spot for the insertion of the needle. Such acupuncture at Liv 2 sedates the liver when it is overcharged with Qi (energy).

If, however, the liver is deficient in Qi, tonification is required and is achieved at Liv 8, a point on the inside of the right leg near the knee.

Similarly, all malfunctioning organs undergo therapy at special points along their respective meridians to increase or decrease their energy flow. Startling to behold is a diagram of man's body designating the minute areas for needle insertion along the 12 meridians!

There are 365 such strategic spots located on the head, body, and extremities. The needles are made of various metals, come in different shapes and sizes, and are pushed into the tissue by a rotary motion to propitious depths, being left there however long the acupuncturist considers feasible—from a few minutes to as much as an hour.

Deceptively simple as the theory of acupuncture may appear, it is amazingly complex, operating under manifold laws, the four major ones being the Mother-Son law, the Husband-Wife law, the Midday-Midnight law, and the Five-Elements law. These laws govern the intricate amphoteric interaction of organ stimulation and sedation, since acupuncture affects not only the single organ being treated but also the neighboring organs on the same meridian.

In ancient China acupuncture was the traditional routine in the practice of preventive medicine. The physician checked up on his regular clients periodically by deftly running his finger along their meridians and noting subtle responses that indicated incipient disease before overt symptoms appeared.

Acupuncture, long confined to China, recently disseminated itself in Western Europe, particularly in France and Germany in the 1930s, where it is still being practiced in conjunction with conventional medicine, chiefly to relieve rheumatic disorders.

According to the Encyclopedia Britannica, however: "There is no known physiologic basis to acupuncture."

Which is not to deny that there might be an as yet *unknown* basis!

Aortic Stenosis and Unexplained Gastrointestinal Bleeding

LEONARD NORDSTROM, M.D.*
JAMES MYHRE, M.D.*
Minneapolis, Minnesota

IN 1958, Heyde and Schwartz,^{1,2} reported for the first time the association between aortic stenosis and profuse recurrent gastrointestinal bleeding from an unknown site. Since then other cases of this perplexing clinical problem have been reported in the literature. Our patient with typical aortic stenosis had twelve hospital admissions for gastrointestinal bleeding.

Case Report

This 71-year-old white male was first admitted to Northwestern Hospital, Minneapolis, Minnesota, on January 8, 1964, complaining of weakness, shortness of breath, melena of three months duration and a syncopal episode one day prior to admission.

On physical examination his blood pressure was 160/90, pulse rate 88 per minute and weight 185 pounds. There was slight cardiac enlargement to the left and a loud harsh ejection systolic murmur heard best over the aortic region radiating to both carotid areas indicative of aortic stenosis. A diastolic murmur was not heard.

The admission hemoglobin was 9.8 grams per cent, SGOT 22 units, hematocrit 32.5 per cent, platelets 553,000 per cu. mm., prothrombin time 13.9 with a control of 12.2 seconds, Lee-White clotting time 11 minutes, and Ivy bleeding time three minutes. The electrocardiogram was compatible with a left ventricular hypertrophy. Upper gastrointestinal x-ray series showed a questionable deformity of the duodenal bulb, and a barium enema revealed large numbers of diverticula. The stools were black and Guaiac-positive for blood.

Surgical exploration of the abdomen was carried out in an attempt to establish the site and etiology of the bleeding. No blood was found in the small intestine but a rather large amount in the large intestine. Since the patient had rather extensive diverticulosis involving the entire colon, *a colectomy with an ilioproctostomy was performed.* Prior to surgery the patient received six units of blood and following surgery four units. He did well after surgery and was discharged on February 23, 1964, with a hemoglobin of 12.6 grams per cent.

The *second admission* occurred on April 20, 1964, because of tarry black stools and weakness. Physical examination was essentially normal except for the murmur of aortic stenosis. Admission hemoglobin was 9.5 grams per cent and the stool guaiac 4+. Stomach and small bowel x-rays were essentially normal as was esophagoscopy and the Einhorn string test. Over the next several days the patient was given three units of blood and discharged on April 24, 1964, with a hemoglobin of 13.5

*University of Minnesota Unit for Teaching and Research at Northwestern Hospital, Minneapolis, Minnesota.

grams per cent.

The *third admission* was on June 2, 1964, for repair of an incisional hernia. The hemoglobin was 11.3 grams per cent.

The patient was *admitted for the fourth time* on July 8, 1964, with the complaint of weakness, faintness and an occasional dark stool. Physical examination was essentially unchanged. The admission hemoglobin was 7.8 grams per cent, the hematocrit 23 per cent and the stool guaiac 4+. Stomach and small bowel x-ray examination was essentially normal, and the Einhorn string test did not localize a site of active hemorrhaging. A transfusion with two units of blood was given and he was discharged on July 11, 1964, with a hemoglobin of 13.1 grams per cent.

The patient was *hospitalized for the fifth time* on September 22, 1964, with the complaints of weakness, faintness and dark stools. His admission hemoglobin was 9.4 grams per cent with a 4+ stool guaiac. Stomach x-ray revealed a gastric diverticulum and a possible duodenal ulcer.

Four units of blood were given preoperatively. At surgery, a large gastric diverticulum and a small posterior wall duodenal ulcer were found. A *subtotal gastrectomy* was performed and, in addition, cholecystectomy for cholelithiasis was carried out. The patient's recovery was uneventful, and he was released from the hospital on October 7, 1964, with a hemoglobin of 12.2 grams per cent.

The *sixth admission* was February 16, 1965, for a complaint of diarrhea. No definite cause could be found for his diarrhea other than probable intestinal insufficiency. This admission was complicated by a gram-negative bacteremia with shock for which he was treated and recovered. His hemoglobin values dropped from 11.8 to 8.8 grams per cent, necessitating two transfusions. The patient was discharged March 3, 1965.

The *seventh admission* was March 6, 1965, for crampy abdominal pains and vomiting. Flat plate of the abdomen revealed distended loops of bowel. The patient was treated conservatively for partial small bowel obstruction. His recovery was rapid, and he was discharged on March 9, 1965.

The *eighth admission* was July 8, 1965, for the complaints of weakness and dark stools. The admission hemoglobin was 8.4 grams per cent, and he had a 4+ stool guaiac. A string test suggested multiple minimal bleeding sites. The patient was transfused with two units of packed cells and discharged July 14, 1965, with a hemoglobin of 11.8 grams per cent.

The *ninth admission* was July 15, 1965, for dark stools. Admission hemoglobin was 10.6 grams per cent. The patient was treated with intramuscular iron dextran (Imferon) and discharged on July 17, 1965.

The *tenth admission* was September 28, 1965, for weakness and dark stools. The admission hemoglobin was 7.8 grams per cent and the stool guaiac 4+. Over the following week he received five pints of blood. He was discharged on October 3, 1965, with a hemoglobin of 11.7 grams per cent.

The *eleventh admission* was June 8, 1966, for dark stools. The admission hemoglobin was 9.2 grams per cent, and he had a 4+ stool guaiac. He received three

units of blood. His hospital course was complicated by a urinary tract infection. On discharge his hemoglobin was 13.3 grams per cent.

The *twelfth admission* was July 7, 1966, for chills and fever of two days duration. Physical examination was essentially unchanged. Blood cultures revealed alpha Streptococcus. A diagnosis of subacute bacterial endocarditis was made. He was treated with 20 million units of intravenous crystalline penicillin per day for six weeks. Shortly after institution of therapy, the patient developed a grade III/VI diastolic blowing murmur along the left sternal border. During his hospital stay, he received two units of blood because of continued occult bleeding. He was discharged August 7, 1966, with the diastolic blowing murmur of aortic insufficiency barely audible. He was well without bleeding up to April 1967.

Discussion

Heyde¹ reported that during a ten-year period he had seen ten patients with calcific aortic stenosis and associated gastrointestinal bleeding of undetermined origin. All patients were between 60 and 80 years of age. Schwartz² cited several other patients with calcific aortic stenosis and gastrointestinal bleeding.

The largest series was reported by Williams³ in 1961. He analyzed a group of 1443 patients with gastrointestinal bleeding and found that 1348 patients (93.5 per cent) had a demonstrable cause for their bleeding, and 5 per cent of them had aortic stenosis. Matched controls showed an incidence of 4.4 per cent. Of these 95 patients with unexplained bleeding 25.5 per cent had an aortic valve lesion, mainly calcific aortic stenosis. Among age and sex-matched controls admitted during this same period, aortic stenosis was present in 5.2 per cent. Therefore there was nearly a five times greater incidence of aortic stenosis in those patients with unexplained gastrointestinal bleeding. Of those individuals with aortic valve lesions, 17 per cent had a positive test for syphilis, 25 per cent had evidence of diabetes mellitus, and most were in the 7th and 8th decade of life. Laboratory studies demonstrated no consistent or gross abnormality by which the gastrointestinal hemorrhaging could be explained.³

Since William's report, other scattered case reports have appeared in the literature. Castleman⁴ described a 78-year-old female who had multiple admissions for gastrointestinal bleeding associated with calcific aortic stenosis. Trowbridge⁵ reported a series of four cases with undetermined gastrointestinal bleeding

and aortic stenosis.

The etiology of gastrointestinal bleeding is not known. Williams³ mentioned several interesting possibilities. He speculated that prolonged diminution of left ventricular output and consequent tissue hypoxia might be the cause for profuse gastrointestinal bleeding. Calcific aortic stenosis may be associated with visceral arteriosclerotic vascular disease, thus predisposing the intestinal tract to bleeding from minimal physiologic trauma such as food and alcohol. It is of interest that most of our patient's episodes of gastrointestinal bleeding were associated with excessive alcoholic intake and/or eating such foods as peanuts. Syphilitic endarteritis in the mesenteric bed could be a cause. In Williams' study there was no pathological material to test this

latter hypothesis.

Summary

This is a case report of a 71-year-old white male with calcific aortic stenosis and repeated episodes of gastrointestinal bleeding from an undetermined site. The patient was hospitalized 12 times, underwent three surgical procedures, and received 35 units of blood. It appears that the combination of aortic stenosis and unexplained repeated gastrointestinal hemorrhage is not just coincidental. It is speculated that tissue anoxia and mucosal fragility from the lowered cardiac output in aortic stenosis, the arteriolar insufficiency of visceral arteriosclerosis, and syphilitic endarteritis are attractive etiological possibilities in this perplexing problem.

It's the Law

Hospital Parking Lot Exempt from Taxation

A trial court granted a hospital's application for declaration that its parking lot was exempt from taxation. The parking lot was built for the sole purpose of providing off-street parking for patients, employees and visitors only, and some effort was made to limit public use of it. Employees were issued cards which admitted them to the lot free of charge. Others paid a fee of 25¢. There was testimony that visitations were considered supportive therapy for patients. If a visitor were unable to pay the 25¢, he would be permitted to park free of charge.

The operation of the lot had resulted in some profit. However, it was clear that the hospital's purpose in operating the lot was not to make a profit, but to provide necessary services and facilities. Thus, its operation was incident to the hospital's major purpose, and the lot was, therefore, exempt from taxation.*

The advance of scientific knowledge as it really happens is not a steady resolute march to the stars. It goes something like this: One step forward, two steps sideways, fall flat on your face. Get up facing backwards, and try to see which way you were going; then repeat da capo.

—Daniel Luzon Morris

Blood-letting

The body had three doors through which it could evacuate noxious matter: through the skin in the form of sweat, through the kidneys as urine and through the bowels as feces. But since there were four juices there must also be four exits. The doctors invented this fourth door in the shape of blood-letting.

Hippocrates first gave blood-letting, within the framework of the juices theory, a scientific foundation; it was held to be the last means of driving the sick juices from the body when sweating, purging and diuretics failed.

In Paris at the turn of the nineteenth century patients were unscrupulously bled. Bleeding from countless incisions, they lay there like the victims of some blood-thirsty sacrifice so exhausted by the heavy loss of blood that they were hardly able to groan. The wounds often became infected and suppurated, so that the sick often died of dermatitis. It was heralded as a great step forward when Broussais conceived the idea in minor cases of blood-letting painlessly with the aid of leeches rather than by opening the veins.

Now it became the fashion, it was believed that the leech was capable of sucking all the deleterious* matter from the body. The demand for these creatures was enormous. Soon every pond in France had been scoured of these valuable worms, and they had to be imported from Bohemia, Hungary and the Baltic countries. Between 1827 and 1836 the Paris hospitals alone used five to six million leeches annually at a cost of a million and a half francs.

France alone needed in the neighborhood of thirty-three million leeches. They lay in readiness in rows of glass containers. The leeches were placed on the belly of the patient in order by their powers of suction to relieve the excess blood of gastroenteritis. Applied in their hundreds they sucked the patient's belly until it looked like a black glittering coat of mail. Full of hope, doctors and patients alike watched the silent activity of their little helpers who, with their greedy suckers, were to draw out the sickness from the body.

The opponents of this method spoke sarcastically of "vampirism," and maintained that more blood was being shed by Broussais' therapy than had been shed during the Revolution and the Napoleonic wars combined. In their irony they lagged far behind the truth. The hosts of leeches which Broussais had conjured up from the slimy depths of ponds and engaged against the human race, for sixteen years in succession, annually sucked 1,680,000 litres of blood from the French people.** If we add the loss of blood from ruthless blood-letting, we reach a figure which makes Broussais the bloodthirstiest man in world history, for at his instigation and on account of his error, twenty to thirty million litres of blood were shed in France alone.

—H. S. Glasscheib, M.D.: *The March of Medicine*, 1964.

*See Test Your Word Score Page 1659.

**A leech can imbibe up to seventeen grammes of blood. After three to four months it is sufficiently hungry to be used again, but it can serve only three times.

Needle Biopsy of the Liver

A Five-Year Survey of the Menghini Technic

DENNIS D. KNUTSON, M.D.*
WINSTON R. MILLER, M.D.**
St. Paul, Minnesota

NEEDLE PUNCTURE of the liver was first practiced in the late 1800's in diagnosis and treatment of hepatic abscesses. In 1939 Iversen and Roholm reported an aspiration biopsy modification as a diagnostic aid in acute hepatitis.¹ In recent years utilization of diagnostic needle biopsy has been limited because the most commonly used Vim Silverman needle requires skillful usage and produces significant morbidity even in the most experienced hands. In 1958 Menghini developed the "one-second liver biopsy" method utilizing a special thin wall, a small bore needle and a rapid aspiration technic.^{2,3} Even an inexperienced physician can apply the method with ease and with little fear of serious morbidity, by the simple expedient of reasonable caution.

The Menghini method was introduced at the Charles T. Miller Hospital by one of us (WRM) in 1961 without previous experience or demonstration. Since then it has been learned by staff physicians and by interns and residents on the service of Internal Medicine.

Method of Study

This paper presents an analysis of our experience with the Menghini needle technic during the five-year period 1962 to 1967. The clinical records of 59 patients subjected to 62 Menghini needle biopsies were studied with special attention to clinical-pathological correlations. The range of age among the 30 men and 29 women in the series was 24 to 85 years. Fifty-six biopsies were intercostal and six subcostal. Among the indications for liver biopsy were unexplained hepatomegaly, jaundice, abnormal liver function studies, suspected primary or metastatic tumor of the liver, or suspected systemic disease. Contraindications included prolongation of the prothrombin time five seconds or more above the control, and congestive hepatomegaly.

*Intern, Charles T. Miller Hospital, Saint Paul, Minnesota.

**Medical Director, Saint Paul Medical Center.

Results

A summary of histologic diagnoses is shown in Table 1.

TABLE 1

Histologic Diagnoses of Menghini Liver Biopsy Specimens

Biopsy Diagnosis	No. of Biopsies
Normal liver	18
Nonspecific hepatitis	1
Cholangiolar hepatitis	1
Pericholangitis consistent with lupoid hepatitis	1
Laennec's cirrhosis	1
Portal cirrhosis	2
Postnecrotic cirrhosis	1
Biliary cirrhosis	1
Cirrhosis (unclassified)	5
Metastatic cancer	7
Fatty metamorphosis	11
Chronic passive congestion	1
Periportal fibrosis	1
Hemochromatosis	1
Hepatic abscess	1
Bile stasis	2
Insufficient tissue	7
	—
	62

Representative laboratory and physical findings in eighteen patients whose liver biopsy showed normal liver tissue are shown in Table 2.

TABLE 2

Results of Liver Function Tests and Physical Findings in the
18 Patients with Normal Tissue Diagnosis

	Total Tests	Abnormal Number	Percent Abnormal
Total serum bilirubin (above 1.1 mg.%)	15	1	6.7
Serum alkaline phosphatase (above 2.3 B.L. units)	12	6	50
Cephalin flocculation (+ 3 or above in 48 hrs.)	8	2	25
Thymol turbidity (above 4 units)	7	3	42.9
Bromsulfalein retention (above 5% in 45 min.)	11	8	72.7
	Number of Patients		Percent
Hepatomegaly	9		50
Splenomegaly	1		5.5
Ascites	2		11.1

Morbidity

There was no mortality and the two cases demonstrating objective morbidity had only a minimal asymptomatic pneumothorax after intercostal biopsy. Five patients had mild pleuritic pain; four had referred shoulder pain from trauma to the diaphragm; and seven complained of mild discomfort at the site of puncture.

All morbidity was transient and required only mild analgesia.

A summary of clinical-pathological correlations is shown in Table 3.

TABLE 3

Clinical-Pathological Correlation

	Number	Percent
Helpful in Diagnosis:	39	66.1
Confirmed the clinical diagnosis	19	32.2
Corrected the clinical diagnosis	20	33.9
Of No Help in Diagnosis:	20	33.9
Noncontributory	13	22
Inadequate specimen	7	11.9

The 12% incidence of inadequate specimens is partially explained by the fact that the operator in most of the cases was learning the procedure. Of the 13 biopsies which were non-contributory to the clinical diagnosis, four were actually misleading, since the normal liver tissue biopsy was followed by proven metastatic hepatic malignancy. In 20 cases (34%) the biopsy corrected incomplete or erroneous clinical diagnoses. Cases in this group included hemochromatosis, hepatic abscess, fatty metamorphosis, hepatic malignancy and normal liver.

Discussion

This study demonstrates the ease and value of the Menghini needle biopsy technic in inexperienced hands. The absence of severe morbidity and the 30% incidence of mild morbidity contrast with a reported mortality of about 0.1%^{4,5} and severe post-biopsy pain in 5 to 20%^{6,7} with other technics. In another study utilizing the Menghini method a 3.2% incidence of severe post-biopsy pain was reported.⁸

A demonstrated diagnostic value in 66% of cases in this series compares favorably with reports of other studies of this type.^{5,8,9,10,11} In seven of 11 cases of metastatic malignancy, the biopsy demonstrated the disease. Conn and Yerger report that needle biopsy will be diagnostic in 50% of all cases of metastatic malignancy of the liver, and positive diagnosis is increased to 90% when clinical signs of metastatic malignancy are present.¹²

It is well known that many cases with mild abnormalities in various liver function tests will have anatomically normal liver tissue by needle biopsy. This was well demonstrated in this series. None of these patients has shown

subsequent evidence of significant liver disease except the four cases with undetected metastatic malignancy.

Summary

The Menghini technic of needle biopsy of the liver was easily utilized by inexperienced physi-

cians as a valuable diagnostic tool. No mortality or severe morbidity occurred in 62 biopsies on 59 patients.

In two thirds of the cases the biopsy gave positive assistance in diagnosis. In one third the histologic diagnosis resulted in revision of the clinical diagnosis. We believe the method deserves more widespread application.

Mr. President—How Is Your Health* John Adams (1735-1826)

Our second President, John Adams, distinguished himself by reaching the venerable age of 90 years, eight months, and four days, a presidential feat unsurpassed before or since, even by Herbert Hoover, who would have had to live five months and 24 days longer than he did to exceed Adams' record.

Up to early middle age Adams was moderately well except for two chronic but not very disabling complaints: "eye weakness," uncorrectable by optometry at that time, and "nervousness," that indefinable but common affliction of sensitive intellectuals.

At age 35 Adams was assaulted by severe chest pain accompanied by chills and fever, the cause of which was not established but from which he recovered—not, however, without psychic trauma; for he ever thereafter regarded himself as a partial valetudinarian: a subsequent eye inflammation and palsied hand vindicating his gloomy conviction of his own infirmity.

When in Paris on official government assignment in 1783 Adams succumbed to an acute attack of influenza which so debilitated him that recovery took eight months. But it was not until he was in his eighties that the irreversible deterioration of old age caught up with him in much impaired vision and hearing, his arteriosclerotic decline thenceforth proceeding gradually and terminating in death from pneumonia on July 4, 1826: an eminent statesman's sad but appropriate commemoration of Independence Day.

*With acknowledgments to Karl C. Wold, M.D.

Pity costs nothing, and ain't worth nothing.—Josh Billings

Living Laboratory

A child had an acute case of xerophthalmia. The doctor found himself in an extremely difficult situation. He had to tell the little patient's mother that her boy, who had already lost his right eye, would inevitably lose the left eye as well.

The doctor was recording the results of his examination with a tarrying hand, putting off the moment when he would have to tell the mother the distressing truth.

But just as the doctor was about to break the terrible news of the boy's imminent blindness, a sudden idea crossed his mind. And what he said was not what he had initially intended to say.

"Bring him to our clinic at three today," he told her. "We'll see what we can do. But don't be late."

At three sharp the boy was hospitalized. A week later he was discharged. He walked down the street holding his mother's hand, and looked up at the shapes of passers-by, at the buses and houses about him.

His right eye was beyond repair. But the second eye was out of danger. It no longer looked lifeless. Its tissues had regained normal luster, and complete recovery was a certainty.

The doctor's sudden idea, which saved the boy from total blindness, hinged upon a blood transfusion, a rather unusual blood transfusion.

There is a class of substances whose presence in man's diet is absolutely essential. They are called vitamins. One of them is vitamin A. It occurs in animal fats, and is particularly plentiful in cod liver oil. But what is most important to us at this point, vitamin A cures xerophthalmia. But at that time vitamin A was not as yet being produced in a form that could be injected into the blood, or subcutaneously.

The doctor's sudden idea boiled down to a method of supplying the child's organism with the required amount of vitamin A. Two hours before the transfusion the donor was made to drink a whole glass of cod liver oil.

At the moment of the transfusion the donor's blood was saturated with vitamin A, absorbed from the intestines. A test made beforehand at the laboratory confirmed this. Along with the transfused blood the boy's body thus received a dose of vitamin A which proved big enough to terminate the xerophthalmic process. It saved the child's eye.*

Remedies for Jaundice

For the cure of jaundice, the ashes of a stag's antlers are employed; or the blood of an ass's foal, taken in wine. The first dung, too, that has been voided by the foal after its birth, taken in wine, in pieces the size of a bean, will effect a cure by the end of three days. The dung of a new-born colt is possessed of a similar efficacy.

—Pliny

There are three kinds of people in the world: the wills, the won'ts and the can'ts. The first accomplish everything; the second oppose everything; the third fail in everything.

—Eclectic Magazine

The Brain

Some Psychobiologic Groundrules for the Lifegame

ROBERT E. BUCKLEY, M.D.
San Francisco, California

IT IS A BASIC principle of logic that every functioning system has its own set of "ground-rules" which allow it to continue functioning. Whether the system we are talking about is a social organization, a steam engine, or a living animal, there are going to be certain basic consistencies in their functioning. Each system will have an energy source to activate it, an arena or field in which to function, and control mechanisms to limit activity.

Governor Mechanism

The brain has basic and fundamental rules which describe the way it regulates the biologic energy which activates it. It has multiple control systems which stimulate and inhibit the function of interconnected areas. These impulses then blend and fuse into coordinated behavior.

In order to explore the fundamental rules which are functioning in the brain, it will be necessary to first describe some of the negative and positive limbs of feed-back circuits in a simple machine like the steam engine. The energy input which drives this machine is heat, which raises the steam pressure of the boiler and activates the piston to accelerate the drive wheels. When these wheels reach a pre-determined speed, they will activate a governor which will decrease the energy input, so that the machine will not exceed its critical limit. Likewise, the influence of positive and negative feed-back factors is a matter of primary importance in understanding the effect which the basic brain systems have on each other.

The Human Brain

The human brain can be described as containing three brain systems which are superimposed, one upon another. Paul MacLean has described these as the reptile brain, the early mammal brain and the primate brain (late mammal).¹

The Reptile Brain

The area which he describes as the reptile brain is the brain stem, and contains the motor nuclei of the cranial nerves, and the reticular activating system which determines the activity of the sleeping-waking cycles and the primitive basis of "consciousness." Centers here regulate blood pressure, heart rate, digestion, and even the movement of the eyes. Some rather simple or primitive aspects of sexuality, such as penile erection, are represented here, along with nuclei which are parts of circuits dealing with balance and equilibrium. The motor cells of the primate brain stem are principally activated and controlled by influences which descend upon it from higher areas which developed later in the course of evolution. The metabolic activity of the reptile brain is more primitive than that of the early mammal brain. Both of these brain systems have a lower uptake and utilization of oxygen and carbohydrate than the primate brain.² We would naturally expect that the enzyme systems which regulate metabolism will be different in the reptile and the mammal brain, since the reptile brain will still function at temperatures which are much below those which the mammal brain must have for optimal function. It is useful to recognize this primitive metabolic potential of the brain stem, because it helps us to understand why it can still function when other areas of the brain have been inhibited and the patient has become comatose.

Early Mammalian Brain

The second system is the early mammal brain, also called the Limbic System, which includes two rather complicated pathways connecting the hypothalamus with the temporal lobe nuclei. It contains the structures which were previously called "the rhinencephalon", or literally the nose brain. These are circuits which connect the olfactory nerve* with areas which are related to feeding, fear, and sexual arousal. The glucoreceptor mechanism is situated in the center of the hypothalamus and has a very important effect on nearby nuclei. These happen to include some which are involved in the activities associated with the sense of smell in early mammals.

Late Mammalian Brain

These circuits have remained during the course of evolution, and by the time the primate brain has evolved, they have become circuits involved with emotional experience. The glucoreceptor mechanism is located principally in the ventromedial nucleus of the hypothalamus and is activated by elevation of the blood sugar to inhibit the activity of the nearby feeding mechanism in the lateral hypothalamus.³ When this occurs, the animal stops feeding: a remarkably clear illustration of the negative feed-back limb of a complicated circuit. This circuit involves activation of the feeding drive as the glucoreceptor mechanism becomes inactive because of food deprivation and initiates behavior which results in eating. This will elevate the blood sugar and activate the glucoreceptor mechanism. When it is activated, it acts in a manner similar to the governor of a steam engine and reduces the energy input into the system through the inhibition of the feeding drive, thus initiating a period of food deprivation and the start of another cycle.

Drive Behavior

This gives us an opportunity to define the meaning of "drive behavior" in psychiatry.

Drive Satisfaction

It is behavior which results in a change of the input into the central nervous system, so that a negative feed-back circuit is activated and an excited area of these emotion circuits inhibited. The process of activation of the negative feed-back mechanism is called "drive satisfaction."

Waking Center

The posterior hypothalamic area is also and simultaneously a part of the reticular activation system of the brainstem and contains a waking center.⁴ The feeding behavior of infants reveals the influence of the glucoreceptor mechanism on the waking center. When the ventromedial nucleus is activated by elevations of blood sugar following feeding, it sends out inhibitory impulses to the posterior hypothalamus and inhibits the "waking center", causing the infant to fall asleep. As the infant brain matures to

*See Test Your Word Score Page 1659.

childhood, more influences begin to affect the posterior hypothalamus, and it is not so regulated by the influence of the blood sugar on the ventromedial nucleus. The influence can still be found in the "siesta effect" which a heavy meal has, even on adults. *In order to evade the sedative effect of eating, it is necessary to increase the sensory input into the reticular activation system with physical activity in order to keep the posterior hypothalamus aroused.*

The Anterior Hypothalamus

The anterior area of the hypothalamus is oriented toward the activities of the parasympathetic division of the autonomic nervous system. Stimulation here with depth electrodes will activate the mucosa of the stomach and increase the production of gastric acids when the vagus nerve is intact. This is associated with the development of peptic ulcers.⁵ When the disease of diabetes occurs, it causes a chronic elevation of the blood sugar which activates the ventromedial nucleus. If the relationship exists with the anterior hypothalamic area which we have found with the lateral and posterior areas, we would expect that diabetes should protect against peptic ulcers. In fact, it does. The rate of peptic ulcers in the normal population is four to five times as high as the diabetic population.^{6,7}

The various circuits within the limbic system have been described differently by different observers, but they do basically agree that there is a circuit which connects the anterior hypothalamus with the amygdala, and another which links the posterior hypothalamus with the hippocampus. MacLean has designated these as circuits associated with self-preservation and species preservation.⁸

The Primate Brain

The third system of the human brain which we can focus on has been called the primate brain consisting of the neocortex and the thalamocortical circuits which connect it with the lower two systems. Its influence on these lower centers, particularly the posterior hypothalamus which is part of the reticular activation system, is to provide an inhibitory control of impulsive and aggressive behavior. This

is why decortication of animals is associated with the development of "sham rage."^{*} These animals are constantly on the verge of aggression and are very likely to attack anyone who increases the sensory input into the reticular activation system. Direct electric stimulation of the posterior hypothalamus can also elicit "sham rage" and cause changes in blood sugar identical to those caused by the emotion of fright or anger.⁹

Disturbed Cortico-Thalamic Circuit

This factor is of great importance in understanding the inappropriate and impulsive rage behavior of senile elderly patients. The basis of their consistently being on the verge of "sham rage" can be found in the loss of physiologic activity of the cortico-thalamic circuits associated with cortical atrophy. The cortex of the brain, the last portion to evolve and the last to become myelinated and then mature, is the most sensitive to the biologic stress of aging. While the more hardy and simple metabolic activity of the brain stem continues to function, the cortex is subject to physiologic inhibition and eventual atrophy.

The activation of the sympathetic functions of the posterior hypothalamus will be influenced by the cortico-thalamic circuits, which influence the reticular system, and circuits of the limbic system, particularly one which connects the amygdaloid nucleus of the temporal lobe with the ventromedial nucleus of the hypothalamus. The ventromedial nucleus is an intrinsic part of the glucoreceptor mechanism and has a distinct inhibitory effect on the posterior hypothalamus. The smoothly integrated functions of these circuits associated with both the limbic system of the early mammal brain and the primate brain are required to permit appropriate goal-directed behavior.¹⁰

Chronic Brain Syndrome

It is this event which can allow us to understand the paradoxical response of the senile, and many of those with chronic brain syndrome, to the barbiturates, which act to sedate the neocortex of the brain as well as the reticular system. When this occurs in an elderly person on the verge of "sham rage," he is frequently "stimulated" into impulsive, confused, and usually angry behavior.

^{*}See Test Your Word Score Page 1659.

Behavior Pattern

The recognition of these basic groundrules for the experience of life can be of considerable help in understanding more about basic patterns of behavior.

Love and Contentment

The effect of the glucoreceptor mechanism provides us with some neurophysiologic insight into the oral phase of infancy. Psychoanalytic theory has emphasized the significance of feeding and sucking as reassurance of love and expectation of contentment. Successful experiences at this stage of development have been said to be basic to the development of trust. These theories can be placed in a much better physiologic perspective when the influence of the glucoreceptor mechanism of the ventromedial nucleus of the hypothalamus is considered: the circuit which is activated by the elevation of blood sugar resulting from the oral feeding activity. This event will inhibit

both the activity of the feeding area of the lateral hypothalamus and also the activity of the posterior hypothalamus, an area principally associated with the activities of the sympathetic division of the autonomic nervous system. Activation of this area has been shown to cause "sham rage" behavior.⁹

When we recall that the newborn infant is basically a "brain stem preparation" actually functioning in a state similar to decortication, we can begin to understand his action and emotion when hungry. The glucoreceptor mechanism is unable to function following food deprivation. This reduces its capacity to inhibit surrounding areas and they are released to express the primary activity which occurs on stimulation. The state of food deprivation then releases the posterior hypothalamus and the "waking center" is activated, awakening the infant. Stimulation of this area can be associated not only with "sham rage" but also with hyperactivity, destructive behavior, anxiety, or fear. This is why the infant appears to be so angry when he cries.

Figure

The three basic brain systems which fuse and blend in the adult brain to permit coordinated, goal-directed behavior.

The anger is an inevitable part of the activation of the hypothalamus which is a part of his feeding cycle. The act of sucking will become a part of a conditioned response in which relief from emotional distress will soon follow.

Feeding and Relief from Anxiety

To a certain extent, we can find a neurophysiologic basis or background for some theories about early infancy. Feeding is associated with relief from anxiety. But to the extent that this observation is valid, it simultaneously invalidates any neurophysiologic importance to the concept of "anality." Sucking and feeding will elevate the blood sugar and have some profound effects on the emotional circuits of the rhinencephalon of the limbic system. Defecation cannot have such an effect. A bowel movement may occur after stimulation in some areas of the brain, but this action has more similarity to the movements of the hand in Jacksonian epilepsy than it does to an important emotional event, such as activation of the glucoreceptor mechanism.

Maturation of the Brain

As we consider the gradual development of the child's brain, we find that at the age of four it has finally achieved about 90% of the weight it will have as an adult brain.¹¹ This is the approximate period of time that the child is learning to control his aggressive behavior. He is now learning to accept and identify with rules. It has been found that while activation of the posterior hypothalamus can cause aggressive behavior, this is associated with the medial area. The lateral area of the posterior hypothalamus is excited by testosterone, and activation of it is associated with sexual arousal and orgasm.¹²

This, then, provides us with an organic, neurophysiologic explanation for the development of sexual guilt. As the child learns

rules of behavior and safe limits are set for him to grow in, he must learn to inhibit his aggressive impulsiveness. The continuing maturation of his cortex is finally providing him at four or five years of age with a psychobiologic mechanism which can control and inhibit the posterior hypothalamus. It can be proposed that this inhibitory process physiologically *includes both the medial and the lateral hypothalamus*. The child then will develop a sense of guilt about sexual arousal or curiosity which will be comparable to his guilt about aggressive or "bad" behavior. He need not ever have been threatened or punished for any sexual actions. He will develop a sense of sexual guilt because the inhibitory influences of the cortex have been placed on the entire posterior hypothalamic area. It is of interest that the Rorschach responses of children also change during this time, and some of the impulsiveness of earlier records is now shadowed by doubt. This is the phase of development that Freud identified as the Oedipus conflict.

To the extent that this is correct, it can help us to understand the universality of an almost compulsive need to masturbate during male adolescence. This could be the mechanism by which the blanket inhibition of the area during childhood is altered, so that sexual arousal can be integrated into a guilt-free area of personal behavior.

Conclusions

This review of three identifiable systems in the brain provides us with some psychobiologic ground rules to use when we consider the meaning of different factors which influence behavior. To recognize the location and connection of various circuits can help us to better understand and predict behavior and symptoms. It can also help us to recognize factors which we might want to augment or diminish in order to change behavior and relieve symptoms.

A Wharf Rat

We could never tell where ambulance calls would take us, but one thing we knew—there would be a policeman waiting at the other end of the telephone, for all the calls were sent in by the police.

One brilliant day in early spring with a sting of frost still in the air, a call took me down to the docks and onto a big sailing vessel anchored there. While rigging up their sails that morning the sailors had come upon the crushed body of a little boy possibly eight years old, high up, hidden in the folds of one of the biggest sails. There was no doubt that he was dead, and that freezing had overtaken him up aloft in the sails. Was his death due to an accident or murder? Did anyone know the boy? What was his name? The police scouted the theory that it could be foul play. An old stevedore came along and stopped to see what the excitement around the ambulance was all about; he edged in to the little group and when the policeman asked, "Can anyone identify the boy?" he said, "Sure, I know that kid—he's a little wharf rat."

"Do you know where he lives?"

"Sure, he lives along the docks here hiking from slip to slip."

"Do you know his name?" the policeman persisted.

"He aint got no name that I know of, but we all give him a break when we got it, with grub and clothes."

This laconic information seemed to satisfy the police, who figured that he had climbed up into the folds of the big sail for a night's rest and during the night the wind had changed and the big boom had shifted its position, crushing the little boy to death in his sleep. No one seemed surprised or concerned, for he was just a little wharf rat.*

(President's Letter continued from page 1613.)

to the Editor", or some such response to my discourse. What I have said about our own Medical School could be said about most other schools in this country, I am sure.

I should like to take advantage of this space to say a great "Thank you" to Dick Magraw for what he has started here at the University of Minnesota. We wish him well in his new endeavor, and are pleased that he will be in a policy-making position, where his type of attitude is sorely needed. I am confident that he will not lose the excellent perspective which

he now has, even though he moves up to the Federal level. He will make his voice heard, in his own quiet, persistent way.

Traumatic Brain Syndrome

Psychological Sequelae in a Case Undergoing Remission

WILLIAM T. LUCKEY, M.D.
Minneapolis, Minnesota

A FEW YEARS AGO a patient's wife told a social worker who was making a home visit: "I feel my intentions have been misinterpreted by your clinic. I was told that he would never get along outside the hospital and that it might be better if I tried to forget him. It is not true that I don't want him to come home; I simply feel that if he does, there will be many adjustments to make by all of us."

Her husband was leaving the hospital (a chronic psychiatric institution) for the first time since a near fatal accident, which had occurred in 1960; he had been continually hospitalized for a period of four years. His diagnosis was that of chronic brain syndrome due to head trauma.

This particular case is important for two reasons: first, it demonstrates the difficult social and intrapersonal problems that may face a patient who was once considered hopelessly disabled but who is now slowly recovering. Second, it reminds one again of an old clinical axiom which one of my neurology instructors used to repeat over and over: "Don't ever give up hope for some latent recovery in even the most severe head trauma—and be ready for some surprises."

Case Report

This 46-year-old white male was involved in an aircraft accident in 1960 while on active military duty. At that time, according to his service records, he suffered severe head trauma and was in a comatose state for about one month after the accident. After regaining consciousness, he had grand-mal seizures which had to be controlled eventually with Dilantin. After the first year it was felt that he had "stabilized;" however, he was considered markedly impaired mentally and emotionally.

Personality Changes

Gross personality changes included frequent mood swings and uncontrolled hyperactivity; severe memory loss, disorientation, and impaired judgment were present on repeated mental status examinations. At this point his wife was told that his chances for ever living outside the hospital were slim and that it might be best if she began to rearrange her life accordingly.

Family Status

The patient was the second of four siblings (having three sisters); there was no history of mental problems in his family or his wife's family. He had graduated from high school and planned a career in the service. He had four children and no history of marital problems; neither he nor his wife had needed psychiatric help prior to his accident. Both he and his wife considered their marriage successful. The patient, at the time of his accident, was working in a supervisory capacity, directing 50 or more men in his department.

Since his hospitalization at a mental institution, the wife had started seeing another man. She lived in a modern, roomy, middle-class home, paid for by the patient's service compensation; the patient used about thirty dollars of this each month at the hospital. She had remained on good terms with her mother-in-law, but not with other family members on the patient's side. One of his sisters felt strongly that the present situation was regarded favorably by the wife and that she did not actually want her husband released. She had not been adept at handling finances and she had been forced to borrow money over the preceding few years to meet expenses.

The patient was released to a foster home after four years of hospitalization. Although still showing marked memory deficit and personality change, his mental condition had "improved." He spent the next few months in a Veteran's Day Treatment Center; during this time he did not work or take part in activities. His attendance rapidly became sporadic and his case was closed after six months; it was later discovered that he had moved to another state and had held a job for about a year before returning to this area.

Clinical Improvement

Upon returning, he again contacted our outpatient clinic. There now seemed to be a marked improvement in his condition; he was less impulsive, more active socially, and much of his memory deficit had cleared. This clinical improvement was verified by comparison of his present psychological test results (1966) with those in 1964 (his first period of treatment at our clinic). The two Minnesota Multiphasic Personality Inventory profiles were of the same basic type (1348), but the current one was entirely within normal limits. In 1964 he had an age-corrected Shipley-Hartford I.Q. of 108 (a verbal raw score of 34 and an abstraction raw score of 18); now his total Shipley-Hartford I.Q. was 125 with a 34 verbal raw score and a 30 abstraction raw score. A Wechsler Adult Intelligence Scale was also administered and showed a full-scale I.Q. of 126; this again verified the marked improvement since 1964 (primarily due to higher performance, as the verbal score had remained the same).

The patient acknowledged that he was "feeling better;" however, he saw himself as "permanently disabled." He was now planning to accept life-long unemployment; he spoke of wanting to work, but he

could foresee only failure if he tried. When reference was made to his improvement, he attempted to *emphasize* the residual problems with his memory and judgment; in short, he saw himself as chronically ill and seemed to resent being pushed back into a "normal life." Several staff members jointly agreed that psychological factors (his poor self-image, his fear of failure) were now more inhibiting than his residual cerebral dysfunction. For the first time, he began to resort to somatic concern when faced with task responsibility at the day treatment center.

His wife still stated that she would take him back into the home if his improvement continued; our impression was that she feared negative reaction by the patient's family and the clinic, and would probably accept any good reason to delay this return. The patient wanted to return and spoke of increasing his contact with the family. He felt, however, that the greatest roadblock to his being received back into the family was their acceptance of his "irreversible problem." He was asking his wife and children to consider him an "invalid."

Psychiatric and Social Implications

This case demonstrates three important psychiatric variables in chronic head trauma cases:

Improvement

Organic brain syndromes can undergo considerable improvement. In cases of trauma, especially in patients with good pre-morbid history, the possibility of latent recovery should be considered in advising relatives.

Marital Adjustment

The spouse of such a patient must (at least temporarily) build a new life; how he or she plans their future may depend upon what the physician says about the possibility of recovery. In this case, therapists at our clinic disagreed over the wife's adjustment and basic motivation. Some felt that *latent* marital conflict was at the root of her attitude and behavior toward the patient, while others saw her adjustment as a reasonable means of survival for a woman faced with such a problem. It was generally agreed that she had at first resigned herself to the idea that her husband would always remain in the hospital.

Psychological Survival

Traumatic encephalopathy may impose distinct psychological problems upon a previously stable personality; these psychological prob-

lems may not be solved when the encephalopathy improves or disappears. With recovery the patient's self-image seems particularly vulnerable; he may begin to show a fear of failure in attempting even minor tasks and speak of himself as a totally "different" person. Minor disabilities may be utilized to avoid responsibility once readily assumed. If in constant association with other chronically ill patients (of various etiologies) during his recovery phase, he may learn new symptoms, such as somatic concern. If such a patient once gives up on himself and tends to adapt his goals to those of a dependent, unemployable person, he may even fight to maintain what to him seems the safest means of survival.

Comment

Such a case forces the therapist to make value decisions which influence the lives of the patient, his spouse, and his children. Although there will probably never be any set formula for handling such a human crisis, this case and others have shown me that there may be some guidelines for the clinician to follow.

Repeated, early evaluations of the neurological and psychological deficit are important for both the physician and the family. There is, in my opinion, a definite psychological lift when a spouse knows that a hurried decision about a bad prognosis has not been made.

Of course, one cannot guarantee a family that improvement will occur. But it seems best to suggest that the spouse wait for a period of two or three years before planning a life independent of the patient. I suggest that the physician ask the spouse to wait out this time for a final evaluation (and prognosis).

If the spouse refuses to wait, this can probably be accepted as a rough test of motivation. Under these circumstances, one should probably plan initially to create for the severely injured patient a new life outside his family, since eventual improvement by the patient would be unlikely (by my experience) to influence the spouse's original decision.

If the spouse voluntarily waits, I feel that some psychological help should be given by hospital or outside medical personnel. The spouse should be well aware that total recovery is unlikely to occur, and that the interpersonal

relationship will probably never be the same as before.

With evident improvement the family must still be allowed to make their own decision about taking the patient back into the home. At the end of the waiting period, all aspects of the neurological and mental status should be discussed with the family. If possible, they should accept the patient for several trial periods at home. If they appear able and willing to cooperate, family counseling should be instituted (including the patient).

If the family is unwilling to accept the patient, I do not feel that either professional or social pressure should be used on the family. I have never seen this help either the patient or the family. It has served only to decrease the precarious self-esteem of the patient. Let the relatives make their own decision based on an honest medical evaluation; it is far better to gear the patient for a life independent of the family if he is not truly welcome back.

Most physicians do not like to make such value decisions; however, in chronic traumatic cases this may lead to great interpersonal suffering for a patient's spouse and children. If the patient *does not improve*, I would encourage eventual separation; guilt feelings on the part of the wife should not be allowed to influence her decision. When there are children, a severely disabled patient may be an indifferent or actually cruel parent; and he may often act in a parasitic fashion toward the spouse. After seeing several examples at first hand, I feel that one is obligated to consider and render judgment on whether a spouse should accept a permanently disabled patient back into the family. If need be, psychotherapy sessions should be recommended for the spouse and children with the goal of complete separation from a severely brain-damaged patient.

For a husband and wife who have been married for some time, I do not feel that waiting for several years is an unreasonable request by the physician. Such a sacrifice of time by the spouse is only humane; it also may prevent rash and on-the-rebound behavior. I also feel just as strongly about blindly forcing a spouse and children to accept a severely disabled patient back into their home; for the sake of the children, it may be the duty of the physician to work for a permanent separation.

Medical Quackery

"PHYSICIANS, AS conservators of the public health, are bound to bear emphatic testimony against quackery in all its forms."

Is this a quote from proceedings of the American Medical Association's Clinical Convention in Philadelphia?

The meeting was in Philadelphia, but the year was 1847!

So you see, from its very inception 118 years ago, the American Medical Association has been battling quackery and it is dedicated to a continuation of this warfare against wasting the nation's health and its health care dollar . . . of fighting fraud at the bedside of ill and desperate people.

For, as long as there are human beings, there will be human nature . . . and quacks—pretenders to ability they don't possess—to take advantage of the fact.

The health quack is not so easy to spot these days. The stovepipe hat and the pitchman's hawking have gone. In their place are their space-age counterparts, the suave apparently-sophisticated super salesmen with the Madison Avenue manners.

These merchants of menace, more insidious and unscrupulous than ever, have many new products, worthless diet fads, worthless food supplements, worthless cosmetic devices and treatments, worthless "cures" for everything—even into the area of brain-damaged children and other mental illness.

They bilk the undiscerning—the uninformed, the desperate, the unsuspecting of all ages—of

millions of dollars a year. The estimates of the costs of medical quackery are at best calculated guesses, but they have gone as high as a billion dollars a year. And one authority in the field of quack-fighting has stated that "medical quackery each year costs more lives than all crimes in the United States."

It is the cost of life—and health—that has placed America's physicians in the front lines of the war on quacks. It is the insidious side effect of quackery with which medicine concerns itself—the delay in proper medical care that may cost life itself.

It is for this reason, too, that the medical profession is dedicated to education of the people about cultism.

The House of Delegates of the American Medical Association said in 1933: "Either the theories and practices of scientific medicine are right or those of the cultists are right and those of scientific medicine are wrong, or the theories and practices of the cultists are wrong." And in 1961, it said: "There can never be a majority party and a minority party in any science . . ."

After the quack or the cultist has extracted his pound of flesh—after the damage is done and after the sick may have become the dying because of the delay in proper care—scientific medicine usually is called upon to pick up the pieces.

Medicine has tried and will continue to try to do that job, too, but how much easier the job would have been—how many lives would have been saved—if . . .

American Medical Association

Medical Men on Postage Stamps

Theodor Billroth (1829-1894), Austrian surgeon, is regarded as the founder of modern abdominal surgery, having performed many successful intestinal resections and enterorrhaphies during his career. In 1872 he made his first resection of the esophagus, in 1873 his first complete excision of the larynx, and in 1881 his first resection of the pylorus. Also performed by him in 1891 was the first recorded interilio-abdominal amputation. In recognition of his phenomenal achievements Austria issued a postage stamp in his honor in 1937.

Robert Picque (1877-1927) was a French army general and military surgeon in World War I, whose pioneer work in surgery at the front was commemorated by France in 1951 on a postage stamp issued in honor of Military Medicine. Along with Picque, portraits of Colonels *Roussin* and *Villemin* also appear on the stamp.

Brucellosis Re-Examined

WHEN SIR DAVID BRUCE concluded his lecture on "The Extinction of Malta Fever" in 1908 he said, "With this chart, which shows the practical extinction of Malta fever, my discourse comes to a close." However, as the Mayo Clinic group points out in a timely review in the October issue* brucellosis is still a perplexing clinical problem.

The clinician must bear in mind that brucellosis is not basically a human disease but a disease of animals transmissible to man. Wherever the disease continues to exist in animals human illness will result. Although the animal brucellosis eradication program in Minnesota has reduced the incidence of the disease remarkably there still exists a reservoir of potential human illness in infected cattle and swine. Brucellosis was detected a short time ago in a flock of sheep in this state.

While human brucellosis appears most often as the sporadic acute or chronic case, epidemics of human cases still occur, mostly due to *Br. suis* and of swine origin. As an example, from June 1966 to May 1967, 43 cases of brucellosis were detected in a meat packing plant in the state of Virginia. Epidemiologic studies on swine introduced into the plant revealed that up to 58 per cent of sows were infected!

In the United States human brucellosis is rarely encountered following the ingestion of dairy products, largely because of the widespread practice of pasteurizing milk. The dis-

ease is primarily an occupational illness occurring in packing plant employees, livestock producers and veterinarians. We have been encountering more and more veterinarians who have accidentally inoculated themselves with the vaccine, *Br. abortus* 19, while immunizing cattle. Because most of these persons had been infected previously with brucellae they had acquired hypersensitivity, and the introduction of organisms resulted in localized inflammation and systemic reactions of chills and fever. Apart from an occasional localized tissue necrosis these individuals recover in a short period with and without antibiotic therapy.

The diagnosis of brucellosis should be suspected in any individual with an ill-defined febrile disease, whose occupation brings him into direct contact with cattle and swine. Sheep constitute a minor problem in the United States. Unexplained lymphocytosis in such patients is a helpful diagnostic aid. The most helpful diagnostic procedure is the brucella agglutination test. Rarely do either acute or chronic cases occur without demonstrable agglutinins. In the World Health Organization Brucellosis Research Laboratory at the University of Minnesota Medical Center the clinical significance of brucella-agglutinating antibodies has been further defined by detecting 7S agglutinating antibodies only in serum from patients with active disease. Furthermore, in contrast with 19S brucella antibody, which is also present, only 7S fixes complement, so that we have found the brucella complement-fixation test highly reliable for detecting evidence of active disease, particularly in the more

DORSEY "FLU-GRAM"

DON'T BE LULLED BY RELATIVE LACK OF FLU LAST WINTER. THIS WINTER BE PREPARED: WHEN THE COMPLAINTS ARE COUGH AND CONGESTION, YOU CAN RELIEVE THESE SYMPTOMS WITH TUSSAGESIC TABLETS. ONE TIMED-RELEASE TABLET AT MORNING, MIDAFTERNOON AND BEDTIME BRINGS UP TO 24 HOURS' RELIEF FROM TROUBLESOME COUGH AND STUFFED AND RUNNY NOSE. TUSSAGESIC IS THE FAMOUS TRIAMINIC FORMULA, PLUS THREE OTHER PROVED CONSTITUENTS. MAKES PATIENTS MORE COMFORTABLE. FAST. ASK YOUR DORSEY REPRESENTATIVE FOR SUPPLY OF STARTER SAMPLES, OR IF FLU IS ALREADY EPIDEMIC, PHONE COLLECT. SEE BELOW.

each

Tussagesic[®]

timed-release tablet contains:

Triaminic [®]	50 mg.
(phenylpropanolamine hydrochloride 25 mg., pheniramine maleate 12.5 mg., pyrilamine maleate 12.5 mg.)	
Dextromethorphan hydrobromide	30 mg.
Terpin hydrate	180 mg.
Acetaminophen	325 mg.

Dosage: Adults—1 tablet, swallowed whole to preserve timed-release feature, in morning, midafternoon and at bedtime. **Side effects:** Occasional drowsiness, blurred vision, cardiac palpitations, flushing, dizziness, nervousness or gastrointestinal upsets. **Precautions:** The patient should be advised not to drive a car or operate dangerous machinery if drowsiness occurs. Use with caution in patients with hypertension, heart disease, diabetes or thyrotoxicosis.

chronic cases and in those with a low titer of agglutinins.

Tetracycline therapy alone is adequate for the majority of cases of brucellosis. The dose is 0.5 Gm. by mouth four times daily for 21 days. In the more severe cases, especially those with suppuration due to *Br. suis*, simultaneous therapy with streptomycin is carried out; 1.0 Gm., intramuscularly once daily for 14 days. For severe and toxic states corticosteroid therapy is advised for three to four days

along with antibiotic treatment. Prednisone in dose of 20 mg. twice daily may be given by mouth.

Two WHO publications are advised for those seeking concise and authoritative statements on the various phases of brucellosis that will appeal to clinicians, laboratory workers and public health personnel. They are: "Laboratory Techniques in Brucellosis" by G. G. Alton and L. M. Jones, WHO Monograph Series No. 55, 1967, Geneva, and "Joint FAO/WHO Expert Committee on Brucellosis", Fourth Report, WHO Technical Report Series No. 289, 1964, Geneva.

Solitary Myeloma (Solitary Plasmacytoma) of Bone*

The relationship of solitary plasmacytoma to multiple myeloma has remained controversial despite many publications. Even the existence of solitary plasmacytoma has not been accepted by all students of the subject.

Solitary plasmacytoma is more frequent in males than females and involves all age groups, with the greatest incidence in the sixth decade of life. Pain often heralds the clinical onset of the disease. It can appear as a swelling which may or may not be painful. The bones most frequently involved by solitary plasmacytoma are the vertebral bodies. Next most frequently involved are the pelvis, femur, and humerus. Pathologic fractures are not uncommon, and paraplegia may occur.

The roentgenographic picture may closely resemble that of a giant cell tumor of bone or a large osteolytic lesion.¹ The former consists of a sharply demarcated osteolytic multicystic area. The area of destruction may be covered by trabeculae. It should be noted that some of the lesions of widespread multiple myeloma may have a cystic trabeculated appearance indistinguishable from that of a solitary plasmacytoma. The cortex is usually intact and no periosteal reaction is seen. The osteolytic type presents a sharp margin. No proliferative bony changes or trabeculae are seen. It is more

commonly found in the spine, and a paravertebral soft-tissue mass may be visible.

The diagnosis rests on histologic proof of a tumor consisting of plasma cells. It should be emphasized that it is impossible to separate solitary plasmacytoma of bone from multiple myeloma histologically.

In addition to histologic proof of a lesion, complete skeletal roentgenograms must show no other lesions of myeloma. It is essential that bone-marrow aspiration show no evidence of multiple myeloma. This examination may reveal increased numbers of plasma cells long before other manifestations of disseminated disease appear. Electrophoresis of the serum should show no "myeloma spike." Rare exceptions to this can occur; an example is Lane's² patient who had a plasmacytoma of the jaw. There was a small peak of gamma mobility which disappeared several months after the tumor was removed. Homogeneous M peaks in the urine on electrophoresis and Bence Jones proteinuria ought to be absent. Although Bence Jones proteinuria has been reported in solitary plasmacytoma, its occurrence strongly suggests multiple myeloma. The presence of anemia, hypercalcemia, increased sedimentation rate, and azotemia suggests multiple myeloma rather than a solitary lesion.

The most controversial criterion for the diagnosis of solitary plasmacytoma of bone is the length of follow-up necessary before one

Eczema of many years... controlled in two weeks

Before treatment

After treatment —
with ARISTOCORT Topical
Ointment 0.1% for two weeks

ARISTOCORT® Triamcinolone Acetonide Topicals have proved exceptionally effective in the control of various forms of eczema: allergic, atopic, nummular, psoriatic, and mycotic.

In most cases responsive to topical ARISTOCORT, the 0.1% concentration is sufficiently potent. The 0.5% concentration provides enhanced topical activity for patients requiring additional potency for proper relief.

Administration and Dosage: Apply sparingly to the affected area 3 or 4 times daily. Some cases of psoriasis may be more effectively treated if the 0.1% Cream or Ointment is applied under an occlusive dressing.

Contraindications: Tuberculosis of the skin, herpes simplex, chicken pox and vaccinia.

Precautions and Side Effects: Do not use in the eyes or in the ear (if drum is perforated). A few individuals react unfavorably under certain conditions. If side

effects are encountered, the drug should be discontinued and appropriate measures taken. Use on infected areas should be attended with caution and observation, bearing in mind the potential spreading of infection and the advisability of discontinuing therapy and/or initiating antibacterial measures. Generalized dermatological conditions may require systemic corticosteroid therapy. Steroid therapy, although responsible for remissions of dermatoses, especially of allergic origin cannot be expected to prevent recurrence. The use over extensive body areas, with or without occlusive nonpermeable dressings, may result in systemic absorption. Appropriate precautions should be taken. When occlusive nonpermeable dressings are used, miliaria, folliculitis and pyoderma will sometimes develop. Localized atrophy and striae have been reported with the use of steroids by the occlusive technique. When occlusive nonpermeable dressings are used, the physician should be aware of the hazards of suffocation and flammability. The safety of use on pregnant patients has not been firmly established. Thus, do not use in large amounts or for long periods of time on pregnant patients.

Available in 5 Gm. and 15 Gm. tubes and ½ lb. jars.

406-G

can be assured that dissemination will not occur. Christopherson and Miller³ used a three-year period without evidence of dissemination for the diagnosis of solitary plasmacytoma, while Pasternack and Waugh⁴ followed their patients from four to 10 years. However, dissemination or recurrence of plasmacytoma has occurred at nine to 12 years,^{5,6} and one case as late as 21 years⁷ after the initial lesion had been found. Thus one's diagnosis of solitary plasmacytoma is not safe for many years. Even the interesting patient described by Ramos, Johnson, and Kling in the July issue cannot be assured that dissemination will not occur. On the other hand, patients without evidence of multiple myeloma 22 and 35 years after histologic diagnosis of solitary plasmacytoma have been described.⁸

Innes and Newall⁹ have reported that 28 of 46 patients with apparently solitary myeloma developed generalized disease, while Tennent¹⁰ found dissemination in 30% of the patients in

his study. Obviously, the number of patients with apparently solitary myeloma who are found subsequently to have disseminated disease will depend on the completeness of the initial examination. Weiner¹¹ found only four instances of long-term solitary plasmacytoma in 563 cases of myeloma.

Treatment consists of irradiation of the involved site after a definite tissue diagnosis has been made. Amputation is not indicated even if the lesion is in the femur or humerus.

True solitary plasmacytoma of bone diagnosed on the basis of (1) histologic proof, (2) absence of any other bony lesion of myeloma, (3) absence of laboratory evidence of multiple myeloma, and (4) adequate follow-up is rare, but I believe that it does exist. The patient with solitary plasmacytoma must be considered suspect for many years, and even then one is never absolutely certain that dissemination will not occur.

Viral Encephalitis

EACH YEAR in the late summer and early fall, physicians in the area of the Mississippi Valley see many youngsters and adults who present with an acute encephalitic picture. All too often the exact cause of these illnesses is not delineated, even though efforts are made to isolate the virus or demonstrate a significant antibody rise or both.

Recently, evidence has accumulated that California virus is endemic in this area, and the number of reported cases has increased remarkably over the past several years. Drs. Johnson and Rogers* wisely point out in their excellent article that this rise most likely reflects increased awareness of the California virus rather than a truly increased incidence.

The importance of establishing etiologic diagnoses in cases of apparent viral encephal-

itis cannot be overemphasized. This is important not only from the epidemiologic and public health standpoint but also from the standpoint of increasing the understanding of the clinical course of each of the various viral encephalitides. As the authors point out, facilities are now widely available for physicians to pursue these problems to better definition.

Certainly these patients should be carefully studied not only for enteroviruses, herpes, mumps, western and eastern equine, St. Louis, and Powassan viruses, but also for California virus. By doing so the physician should increase his diagnostic achievement considerably.

Lymphangiography: Value in Determining the Extent of Disease in Patients with Lymphoma*

THE LACK of accuracy which limits the use of lymphangiography for the detection of lymph node metastasis should in no way be misconstrued to discredit the value of lymphangiography in determining the extent of the disease in patients who have lymphoma (Hodgkin's disease, lymphosarcoma, and reticulum cell sarcoma). Gross abnormalities of lymph nodes are detected by lymphangiography, but frequently microscopic metastatic involvement is not detected. Lymphoma, however, usually enlarges the involved lymph nodes and diffusely alters the architecture. Such changes are so definite that they are readily detected roentgenographically after these lymph nodes have been opacified with contrast mediums used for lymphangiography.

Lymphangiography has proved to be the most accurate method for assessment of iliac and retroperitoneal lymph nodes for the presence of lymphoma. In fact, lymphangiography is of such value that the Committee on the Staging of Hodgkin's Disease, at a conference sponsored jointly by the National Cancer Institute and the American Cancer Society (Rosenberg, S. A.: Staging of Hodgkin's Dis-

ease. [Letter to the editor.] Radiology 87:145, 1966) recommended the routine use of lymphangiography for all patients who have Hodgkin's disease to determine the extent of the disease.

Lymphangiography assumes its most crucial role when performed as part of the work-up of patients who have clinically localized lymphoma, stage I or II. Lymphangiograms will reveal lymphoma involving the para-aortic and iliac lymph nodes in some of these patients, a finding which demonstrates that a more advanced stage of disease is actually present.

When initial clinical evaluation shows that a patient has generalized lymphoma, lymphangiography is usually of no practical value because plans for treatment will generally not be altered by the result.

Because lymphangiography is a reasonably accurate method for evaluating the status of the para-aortic and iliac lymph nodes, use of this procedure would seem to be indicated whenever knowledge as to the presence or absence of lymphoma in these lymph nodes would be important in the management of the patient's disease.

Respiratory Mucosa*

THE ROLE OF the respiratory mucosa is a very interesting one indeed and has received a great deal of attention both from the examination of human material and also from experimental studies. Probably the most significant study is the compilation of material accumulated by the Surgeon General's Committee on Smoking and Health. Although there is much discussion today on the role of air pollutants and their effect on the respiratory epithelium, cigarette smoke has been found to be by far the most damaging.

Non-Carcinogenic Changes

The inhalation of foreign material into the tracheobronchial tree is capable of causing a variety of changes. Basically there are two types of changes which are found following such exposure. If the agent is non-carcinogenic the changes in the tracheobronchial tree will be those of basal cell hyperplasia in which the basal cells have nuclei uniform in size and shape without any definite alteration in the chromatin content. The increase in cells is uniform and orderly, and the cilia on the surface are also unaltered. In response to such stimuli there may also be a loss of cilia with a flattening of the cells on the surface with their nuclei at right angles to the long axis of the tracheobronchial tree. The transformation into this type of epithelium is that of squamous epithelium similar to that which lines the pharynx or mouth. Keratinization on the surface is a rare occurrence in the tracheobronchial tree.

Carcinogenic Changes

Far more important and far more significant are the changes produced by carcinogenic agents, the most important of which result from cigarette smoking. Although the specific elements have not been completely isolated from the cigarette, nevertheless, it is the inhalation of the cigarette smoke that causes

changes found to be present in the basal cells. Here the nuclei undergo alterations in size and shape, irregular condensations of the chromatin and clumping of the chromatin. These cells migrate toward the surface and replace the normal epithelial cells as they progress toward the surface. As the proliferation progresses and the changes become more extensive, the cells take on the characteristic appearance of carcinoma cells.

Carcinoma In-Situ

As the process continues, these atypical cells migrate toward the surface and, with a disappearance of the cilia on the surface, a change occurs which may be designated as carcinoma-in-situ. It is of interest that the inhaled carcinogenic agent produces these changes in all parts of the tracheobronchial tree. The areas of carcinoma-in-situ are frequently present at the sites of bifurcation and least frequently observed in the trachea. In subsequent stages early invasion occurs at the site of carcinoma-in-situ, with the penetration of the basement membrane and extension into the underlying tissue. These invasions are observed more frequently in cases of bronchial carcinoma but are also present in cases where no carcinoma of the bronchus is found. It is of interest that the same changes observed in the epithelial lining of the bronchus are present in the bronchial glands. In some instances the epithelial perforation extends to the surface with a disappearance of all the normal elements within the bronchial glands. Carcinoma-in-situ is also absent in the glands but not early invasion.

Effects of Discontinuing Smoking

Another interesting feature is the regression of changes which occur after individuals stop smoking. A study was done in which 72 cigarette smokers were compared with 72 men who had smoked for at least ten years and had then given up the smoking habit for at least five years. These two groups were compared with another group which had never smoked regu-

in chronic illness

B and C vitamins are part of therapy: An imbalance of water-soluble vitamins and chronic illness often go hand in hand. STRESSCAPS capsules, containing therapeutic quantities of vitamins B and C, are formulated to meet the increased metabolic demands of patients with physiologic stress. In chronic illness, as with many stress conditions, STRESSCAPS vitamins are therapy.

Stresscaps[®]
Stress Formula Vitamins Lederle

Each capsule contains:
Vitamin B₁ (as Thiamine Mononitrate) 10 mg
Vitamin B₂ (Riboflavin) 10 mg
Vitamin B₆ (Pyridoxine HCl) 2 mg
Vitamin B₁₂ Crystalline 4 mcgm
Vitamin C (Ascorbic Acid) 300 mg
Niacinamide 100 mg
Calcium Pantothenate 20 mg
Recommended intake: Adults, 1 capsule daily, for the treatment of vitamin deficiencies. Supplied in decorative "reminder" jars of 30 and 100; bottles of 500.

larly. In all three groups the men were matched as to age, locality and, where possible, occupation. Several interesting findings were observed. There were no zones of carcinoma-in-situ in the individuals who had never smoked. There was a precipitous drop in the areas of carcinoma-in-situ in the former cigarette smokers when compared with men of the same age and same smoking habits who continued to smoke. There was also a precipitous drop in

*Senior Medical Investigator, Veterans Administration.

the number of atypical cells in those who had given up the cigarette habit in comparison with those who continued to smoke.

There is sufficient evidence from the pathologic studies to support the views expressed by Dr. Hilding in his article and to state unequivocally that cigarette smoking today is the single most important factor in the development of lung cancer.

Comparison

The surgeon knows everything and does everything. The internist knows everything and doesn't do anything. The psychiatrist doesn't know anything and doesn't do anything.

—Anon.

Caesarean operation has no relation to the birth of Julius Caesar. The term goes far back into antiquity, and the operation is supposed to have been performed by the early Greeks. The word "Caesarean" derives from the Latin past participle, caesus, from caedere, meaning to cut.

You May Be Right

AT THE RISK of being labelled a bigoted crank, may I take exception to certain statements in an editorial in the January 1967 issue of *Minnesota Medicine* entitled "Why Therapeutic Abortion?" by Theodore Watson.

1. "Saint Thomas Aquinas in the 13th Century held that the soul was directly created by God and infused in the embryo, not at the point of conception, but when the embryo was sufficiently formed to receive it."

Thomas Aquinas described three types of souls: The vegetative, the sensitive and the intellectual soul. He further states that these are "numerically one and the same soul."¹ He did not approve abortion before the development of the intellectual or rational soul.

2. "This allowed the Medieval Church to forbid abortion only after quickening."

There is no historical evidence that the Roman Church ever condoned or acquiesced in abortion at any stage of gestation. Theologians have defined feticide as murder, if the fetus has a human soul. Varying estimates of the moment of ensoulment originate from earliest times. Fourth century theologians, such as St. Basil² and St. Gregory of Nyssa,³ held that the soul was infused at the time of conception and that all abortion was homicide. This concept is not exclusively a "relatively modern one."

In two ways the Church Fathers have proscribed abortion before ensoulment or without direct reference to ensoulment. Since the development of the child from conception to birth terminates with development of human life, direct interference with this process is forbidden by the Natural Law; secondly, by the application of the Principle of Indeterminacy, human life may be present at any point in gestation, and the abortionist must take full responsibility for this possibility.

The Papal Bull, *Effraenatam* by Sixtus V, issued on October 29, 1588, defined severe ecclesiastical penalties for abortion as well as for contraceptive practices. According to Noonan,⁴ Gregory XIV repealed all portions with the exception of abortion of an ensouled, forty-day fetus in the Papal Bull, *Sedes Apostolica*, May 3, 1591. This did not in any sense allow abortion earlier than forty days.

It may be a fair statement that direct abortion before ensoulment was not considered homicide by some Church Fathers (St. Augustine) and possibly a lesser evil with lesser penalties. However, it is not correct to imply that the Church ever considered early abortion anything other than a serious evil.

3. "Pope Gregory V in 1591 designated quickening to occur after 116 days."

Gregory V died in 999. The reference is probably to Gregory XIV, as discussed previously.

In my opinion, it is regrettable that these inaccuracies have appeared in print, especially when they have been quoted verbatim by the local press as authentic historical facts.

Raymond J. Albrecht, M.D.
St. Paul, Minnesota

From a continuing study on nasal congestion...

timed to work while your patient does

A study being conducted by the Department of Otolaryngology, Greater Baltimore Medical Center is stockpiling evidence that points to the fast action and prolonged relief effected by Triaminic in the treatment of nasal congestion.

Begun in March 1966, the study to date has encompassed 85 patients with common nasal disorders—

and measured their response to recommended doses of Triaminic tablets.

Timed to release its oral nasal decongestant and two antihistamines within 8 hours, Triaminic was found to effect partial or complete relief in better than 82% of the subjects treated. Clearing nasal obstruction. Reducing turbinate swelling. Making breathing easier.

It's a comforting thing to know that Triaminic really works.

Triaminic[®] *timed-release tablets*

Each timed-release tablet contains:

Phenylpropanolamine hydrochloride 50mg. Pyrilamine maleate 25mg. Pheniramine maleate 25mg.

Side effects: Occasional drowsiness, blurred vision, cardiac palpitations, flushing, dizziness, nervousness or gastrointestinal upsets.

Precautions: The patient should be advised not to drive a car or operate dangerous machinery if drowsiness occurs. Use with caution in patients with hypertension, heart disease, diabetes or thyrotoxicosis.

The Editor's Soliloquy

The Cults

A system for the cure of disease based on dogma set forth by its promulgator can scarcely qualify as an indispensable health service, nor should any recipient of government benevolence under Medicare be free to choose a system of therapy neither substantiated nor sanctioned by scientific medicine.

If we are to continue to operate a government for the benefit of the people, that government should feel obligated to protect us against health fallacies as well as against other forms of exploitation and chicanery. In the public interest do we not now have such agencies as the Interstate Commerce Commission, the Food and Drug Administration, the Federal Trade Commission, and others operating in their respective fields to protect us from abuses against which we could not individually defend ourselves?

The gamut of health cults runs from ingenuous faith healing to calculated fraud; there have been and may still be extant such "follies" as Autohemic Therapy, Poropathy, and Bio-Dynamo-Chromatic Diagnosis and Therapy, plus 1001 other pseudo-medical practices with no scientific validity. There are pathetically misguided persons who have profound but blind confidence in a copper wire bracelet or a "rheumatism ring" to prevent, alleviate, or cure arthritis; some fanatics ascend 150 steps or more on their knees to reach "miracle" altars or shrines for the cure of their ailments; other gullibles patronize the bonesetter, massager, the mesmerist, or the mere layer-on-of-hands; even the arcane rites of the voodooist or the necromancer can still attract a minority clientele.

Submitting oneself to any type of illegitimate therapy is the prerogative of the individual; but a government should not use tax revenue to support and thereby indirectly endorse such cults. Irrelevant to the issue is the fact that some legislatures may approve licensure of some of the cults.

It is significant that the cults which have been licensed by state legislatures, received the privilege to a limited practice many years ago when the gap between the abilities of the cultists and the medical knowledge of the day was not so wide nor so regrettable as current remarkable developments in scientific medicine have made it today.

It would seem that if many of our honorable United States senators are unwilling to commit themselves unequivocally on this important issue: namely, that of safeguarding their constituents' welfare in the medical field, we may have to become dubious of their sincerity and competence in other areas. Are we to assume that they have not conscientiously informed themselves on this crucial matter, or that they have yielded to the pressures of wily lobbyists? And this despite the fact that experts have advised them that medical cults have no sound scientific basis and should therefore be excluded from the health services eligible for government support!

This is no area for congressional compromise!—Carl O. Rice, M.D.

Old Doc Hess says: Allow those who are familiar with a subject to have their say; they may speak softly—so listen closely!—COR

RICHMOND, VIRGINIA 23217

Manufacturers of ethical pharmaceuticals since 1856

Butazolidin®, phenylbutazone
In Acute Superficial Thrombophlebitis

Contraindications: Edema; danger of cardiac decompensation; history or symptoms of peptic ulcer; renal, hepatic or cardiac damage; history of drug allergy; history of blood dyscrasia. The drug should not be given when the patient is senile or when other potent drugs are given concurrently. Large doses of Butazolidin alka are contraindicated in glaucoma.

Warning: If coumarin-type anticoagulants are given simultaneously, watch for excessive increase in prothrombin time. Instances of severe bleeding have occurred. Pyrazole compounds may potentiate the pharmacologic action of sulfonyleurea, sulfonamide-type agents and insulin. Carefully observe patients receiving such therapy. Use with great caution in the first trimester of pregnancy.

Precautions: Before prescribing, carefully select patients, avoiding those responsive to routine measures as well as contraindicated patients. Obtain a detailed history and a complete physical and laboratory examination, including a blood count. The patient should not exceed recommended dosage, should be closely supervised and should be warned to discontinue the drug and report immediately if fever, sore throat, or mouth lesions (symptoms of blood dyscrasia); sudden weight gain (water retention); skin reactions; black or tarry stools or other evidence of intestinal hemorrhage occur. Make regular blood counts. Discontinue the drug immediately and institute countermeasures if the white count changes significantly, granulocytes decrease, or immature forms appear. Use greater care in the elderly and in hypertensives.

Adverse Reactions: The most common are nausea, edema and drug rash. Swelling of the ankles or face may be minimized by withholding dietary salt, reduction in dosage or use of diuretics. In elderly patients and in those with hypertension the drug should be discontinued with the appearance of edema. The drug has been associated with peptic ulcer and may reactivate a latent peptic ulcer. The patient should be instructed to take doses immediately before or after meals or with milk to minimize gastric upset. Mild drug rashes frequently subside with reduction of dosage. However, rash accompanied by fever or other systemic reactions usually requires withholding medication. Purpuric rash has also been reported. Agranulocytosis, exfoliative dermatitis, Stevens-Johnson syndrome, or a generalized allergic reaction similar to serum sickness may occur and require permanent withdrawal of medication. Stomatitis, salivary gland enlargement, vomiting, vertigo and languor may occur. Leukemia and leukemoid reactions have been reported. While not definitely attributable to the drug, a causal relationship cannot be excluded. Thrombocytopenic purpura and aplastic anemia may occur. Confusional states, agitation, headache, blurred vision, optic neuritis and transient hearing loss have been reported, as have hyperglycemia, hepatitis, jaundice, and several cases of anuria and hematuria. With long-term use, reversible thyroid hyperplasia may occur infrequently. Moderate lowering of the red cell count due to hemodilution may occur.

Dosage in Acute Superficial Thrombophlebitis: Initial: 6 capsules or tablets daily in divided doses for 2 or 3 days. Maintenance: 3 capsules or tablets daily. Usual duration of therapy is 5 to 7 days (rarely beyond 10 days). 6509-V(B)R2

*Stein, I.D.: Presented at the American Academy of General Practice, Dallas, Sept. 1967.

For complete details, please see full prescribing information.

it used to take weeks

Acute superficial thrombophlebitis before treatment

After 5 days of Butazolidin therapy

In acute superficial thrombophlebitis, patients were usually bedfast for 2 to 4 weeks, tying up hospital beds, requiring costly nursing care and time-consuming procedures such as warm soaks and packs.

When Butazolidin was added to the usual regimen, 960 of 1000 patients obtained complete resolution; most required only 30 capsules or tablets; relief of pain and discomfort and regression of inflammatory signs and fever occurred within a few days.*

Side effects occurred in 6% of the 1000 patients. While none were serious or long-lasting, Butazolidin can produce severe side effects in rare instances. Further, not every patient can take Butazolidin. Therefore, select patients with care and follow them closely. Contraindications, Warning, Precautions and Adverse Reactions are summarized in adjacent column.

Butazolidin gets bedfast thrombophlebitics out of bed, fast. Usual duration of treatment is 5 to 7 days, and rarely exceeds 10 days. Try it and see. For full details, please refer to the complete prescribing information.

LOW-BACK PAIN

A CONSERVATIVE, FOUR-POINT PROGRAM

The low back pain that is most frequently seen in general practice is mechanical in nature, i.e., postural back pain, joint dysfunction and acute back strain.^{1,2} For this type of discomfort, a conservative regimen is usually sufficient to relieve aches and pains, and to help keep the patient functioning. Components of this basic program include:

1 Bed "If the patient is in the pain-spasm-cycle...there is no alternative or substitute for absolute bed rest..."³

2 Board "Boards should be ordered under the mattress...these boards act by immobilizing the spine..."⁴

3 Heat "A very valuable method of applying heat at home is a prolonged hot bath..."⁵

4 Robaxin®-750 (methocarbamol, 750 mg. capsule-shaped tablets) A well-tolerated⁶ skeletal muscle relaxant, methocarbamol helps relieve spasm "...without interfering with normal tone and movement."⁷ And there is little likelihood of sedation.⁶

Indicated for relief of skeletal muscle spasm. **Contraindicated** in hypersensitive patients. **Side Effects** (lightheadedness, dizziness, drowsiness, nausea) may occur rarely, but usually disappear on reduced dosage. Hypersensitivity reactions develop infrequently. See product literature for further details. **Also available:** Roboxin® Tablets (methocarbamol, 500 mg.) Roboxin Injectable (methocarbamol, 1 Gm./10 cc.)

Curbstone Consultation

QUESTION: If Hodgkin's disease starts with skin lesions, are there any diagnostic characteristics of such eruptions?

A 56-year-old cattleman developed an acute erythema of both arms and forearms after exposure to 2-4-D. The pruritus was severe. The eruptions subsided with the administration of steroids and local application of olive oil. As the skin lesions subsided, he developed anorexia, nausea, vomiting, weakness, weight loss and leucocytosis. Chest x-rays, upper and lower gastrointestinal studies, intravenous pyelogram, blood serology, sternal puncture, gallbladder x-ray, and brain scan were all negative. Finally, eight months after appearance of the skin lesions, a small supraclavicular node appeared on the right side. Biopsy established the diagnosis of Hodgkin's disease. Did 2-4-D have anything to do with the Hodgkin's?

ANSWER: When Hodgkin's presents itself as a skin disease (lymphogranulomatosis cutis), the skin lesions may be specific or non-specific. The specific lesions may be circumscribed infiltrations or papules appearing in groups on the extremities or the trunk. The histologic changes in these lesions are the same as those found in the lymph nodes of Hodgkin's disease. The non-specific lesions may be urticarial, vesicular, erythematous or may resemble erythema multiforme; exfoliative glossitis may occur. The non-specific lesions may precede or accompany lymph-node enlargement.

It is impossible to state that there is a causal relationship between 2-4-D and the diagnosis of Hodgkin's disease. It would appear that because this substance was used prior to the eruption it was a suspected cause, but not a proven one. There were no patch tests applied; there was no involvement of the face or generalized eruption. According to toxicologists this chemical has a low degree of toxicity. Furthermore, if one were to give an opinion on these meagre facts and state that the material used was the cause of Hodgkin's disease it would have grave legal implications. There are many systemic diseases which have a non-specific cutaneous manifestation, both at onset and concomitant with the symptoms. It is also true that some have specific eruptions which can be demonstrated as such by biopsy. In other words, I don't think I am being of much help, except for giving one man's opinion!

The Viewing Box

Cough and Hemoptysis in a Nineteen-Year-Old Female

THE PATIENT was a 19-year-old white female, who was admitted to the hospital with complaints of weakness, fatigue, lethargy and arthralgia of approximately one month's duration. These symptoms had become progressively worse, and two days prior to admission there was onset of cough, hemoptysis, dyspnea and fever. Physical examination on admission revealed a pale, young white female, moderately dyspneic, with constant coughing productive of bloody-tinged mucoid sputum. Temperature was 103°, respiration rapid, and pulse 140 and irregular. Multiple rales and tubular breathing were heard throughout both lung fields. A tachycardia was present, but no murmurs were heard. Examination of the extremities and abdomen was essentially negative.

Hemoglobin on admission was 4.4 grams per cent with a hematocrit of 15.5 volumes per cent. The white blood count was 12,000 with 91 per cent P.M.N.s, 7 per cent lymphs and 2 per cent monos. Urinalysis revealed smoky appearance, pH. of 5, specific gravity of 1.013, albumin of 4 plus, 5 to 8 white blood cells per high power field and a full field of red blood cells per high power field. Occasional granular casts were also seen. BUN was 87 milligrams per cent. Sputum cultures revealed a moderate number of yeasts, biochemically and morphologically indistinguishable from *Candida albicans*.

Chest roentgenogram (Figure) revealed presence of large confluent areas of density in both lung fields extending outward from the hilar region with the apices and extreme lung bases relatively spared. No pleural effusion was seen. Cardiac size was felt to be within normal limits.

Blood transfusions were given, and the patient was placed on penicillin, chloromycetin and solu-cortef. She remained febrile during the first two days of hospitalization; then the temperature returned to normal. Her cough, dyspnea and hemoptysis progressively worsened, and on the fourth hospital day she expired.

What is your diagnosis? (See next page.)

Figure

Diagnosis: Goodpasture's syndrome.

Autopsy was performed and a subacute exudative and proliferative glomerulitis accompanied by a necrotizing pneumonitis with massive intra-alveolar hemorrhage was found.

The confluent large areas of density in the lung fields seen on admission chest roentgenogram represent massive intra-alveolar hemorrhage. Radiographically, differentiation from other causes of massive bilateral pulmonary consolidation may be difficult, although the relative sparing of the bases and apices may be a helpful differential point. Correlation with clinical findings and history is necessary for diagnosis.

Discussion

Since Richard Bright's classic description of glomerulonephritis in 1836, it has become apparent that histologic glomerular lesions portray a spectrum of diseases with different etiologies and pathogenetic mechanisms. One such variant was first recorded by Goodpasture in 1919, in a study of the pulmonary lesions of influenza. The case was that of a young man who, when recovering from an influenzal attack, had hemoptysis, anemia and albuminuria, and died. Autopsy showed marked pulmonary alveolar hemorrhage and proliferative glomerulonephritis. Stanton and Tange in 1958 reported nine cases of pulmonary hemorrhage associated with glomerulonephritis and suggested the term Goodpasture's syndrome. Since then, there has been a sufficient number of cases reported presenting this disease complex to warrant its being regarded as a specific entity.

The underlying disease process has yet to be clarified. Some have suggested that the changes may be secondary to generalized hypersensitivity reaction which produces an acute necrotizing alveolitis, resulting in repeated episodes of pulmonary hemorrhage. Various drugs including penicillin and antigens have been implicated as possible causative agents. Others have suggested that a pre-existing streptococcal infection might serve as an etiologic factor. The similarity between the pulmonary manifestations of this entity and idiopathic pulmonary hemosiderosis has led to the suggestion that the two conditions may actually represent manifestations of the same pathologic process.

The syndrome predominates in males 9 to 1, and the median age at onset is 21 years. Hemoptysis is the initial symptom in most cases reported and varies from slightly blood-streaked sputum to massive hemorrhage, tending to occur in bouts. Dyspnea and cough are also prominent symptoms. Anemia is always present, even early in the course of the disease. Azotemia is noted late in the disease. Albuminuria and microscopic hematuria are almost always present. Granular casts in the urine have been seen in approximately 50 per cent of the previously reported cases.

The roentgenographic appearance of the lungs is basically the same as that observed with idiopathic pulmonary hemosiderosis. During the acute episode of hemoptysis, there are ill-defined multiple nodular or flocculent densities bilaterally with a perihilar distribution and tendency to spare the apices and bases. These changes may disappear within a few days. Chest roentgenograms taken between the acute episodes show an increase in the interstitial markings characterized by finely granular-appearing reticular accentuation throughout the lungs.

Characteristically, Goodpasture's syndrome is a rapidly fatal disease occurring almost always in young adult males. The median duration of the illness is

about 15 weeks. In absence of specific therapy, steroids have been widely used but the results have often been disappointing. However, there are several reported cases in which steroids have been beneficial in arresting the disease process.

Corpse Blood Transfusion

Take a large medical institution in a big city; say, some first-aid hospital. Look in at the reception ward. You will see that the doctor there is in great demand.

Now picture the doctor on duty, the doctors in the wards, their assistants, and the professor who heads this beehive of activity. They scarcely have time to step away from the operating table.

And late at night a man is brought in who accidentally fired off his gun, and injured himself. The bullet penetrated his abdominal cavity.

The professor takes the man's pulse. It is barely perceptible. There are signs of internal hemorrhage . . . An urgent operation is necessary to suture the injured organs and vessels. An immediate blood transfusion must be made at the same time; if this is not done, the case is hopeless.

All the preparations have been completed. The donor is summoned and is expected at any moment (blood conservation was not known at the time).

But the patient's condition suddenly takes a sharp turn for the worse. The transfusion must be made without further delay. Yet the donor is still on his way.

A daring idea suddenly strikes the professor. A man knocked down by a car has just been brought to the reception ward. He was still alive when he arrived, but dies soon afterwards in spite of the fight they put up for his life. The professor decides to take the blood from the dead man and transfuses it to the gunshot victim.

It is all over within an hour: the operation, and the transfusion as well. The patient's pulse grows stronger as the heart pumps the blood taken from the corpse to all the parts of his body. Certainly, the blood of both the patient and the corpse was tested for compatibility before the transfusion.

All this, but for some minor details, is a true story. It happened at the Moscow Sklifosovsky Institute in 1930.*

Sneezing

Whence comes the custom of blessing and saying "God help" to those that sneeze? We produce three sorts of wind: that issuing from below is too indecent; that from the mouth implies some reproach of gourmandizing; the third is sneezing. And because it comes from the head, and is without imputation, we thus kindly entertain it.

—Michel de Montaigne

Maybe you don't want
your patients to halve Hygroton®chlorthalidone.

Maybe your patients complain:
Why don't they make a tablet I don't have to halve?"

Please see brief prescribing summary at the end of advertisement.

Maybe you abandoned Hygroton_{chlorthalidone} because there wasn't a convenient half strength.

ations: Hypertension and many types of
a involving retention of salt and water.

indications: Hypersensitivity and most
of severe renal or hepatic disease.

ing: With the administration of enteric-
coated potassium supplements, which should
be used only when adequate dietary supple-
mentation is not practical, the possibility of
bowel lesions (obstruction, hemor-
rhage, and perforation) should be kept in
mind. Surgery for these lesions has fre-
quently been required and deaths have oc-
curred. Discontinue enteric-coated potas-
sium supplements immediately if abdominal
distention, nausea, vomiting, or gastro-
intestinal bleeding occur.

With caution in pregnant patients, since
Hygroton may cross the placental barrier and
cause reactions which may occur in the
fetus (thrombocytopenia, hyperbilirubinemia,
and carbohydrate metabolism, etc.) are
potential problems in the newborn.

utions: Antihypertensive therapy with
Hygroton should always be initiated cau-
tiously in postsympathectomy patients and
patients receiving ganglionic blocking
drugs or other potent antihypertensive drugs,
if available. Reduce dosage of concomitant
antihypertensive agents by at least one-half.
Diuretics, narcotics or alcohol may po-
tentialize hypotension. Because of the possi-
bility of progression of renal damage, peri-
odic determination of the BUN is indicated.
Discontinue if the BUN rises or liver dysfunc-
tion is aggravated. Hepatic coma may be
precipitated.

Electrolyte imbalance, sodium and/or potas-
sium depletion may occur. If potassium deple-
tion should occur during therapy, Hygroton
should be discontinued and potassium sup-
plements given, provided the patient does
not have marked oliguria.

Special care in cirrhosis or severe
congestive heart disease and in patients re-
ceiving corticosteroids, ACTH, or digitalis.
Fluid restriction is not recommended.

Side Reactions: Nausea, gastric irritation,
vomiting, anorexia, constipation and cramp-
ing, dizziness, weakness, restlessness, hy-
perkalemia, hyperuricemia, headache, mus-
cle cramps, orthostatic hypotension, aplastic
anemia, leukopenia, thrombocytopenia,
neutropenia, impotence, dysuria, transient
nausea, skin rashes, urticaria, purpura, nec-
rotizing angitis, acute gout, and pancreatitis
epigastric pain or unexplained G.I.
problems develop after prolonged adminis-
tration. Other reactions reported with this
group of compounds include: jaundice, xan-
thopsia, paresthesia, and photosensitization.

Dosage: One tablet with breakfast
or every other day.

Appearance: White, single-scored tablets of
100 mg. and aqua tablets of 50 mg., in bot-
tles of 100 and 1000. (B)46-230-D

**His slovenly room
and habits create
more tension.**

**His disturbances at
the table make every
meal a nightmare.**

**His daughter
can't please him.
There is "just no
living with him."**

See following page for prescribing information.

When the agitated geriatric disrupts the home...

Anxiety that *seriously interferes* with the individual's performance at work, at home, or in the community may be regarded as *moderate to severe* in degree.

Mellaril often recommends itself to the treatment of moderate to severe anxiety because it

- helps control the most frequent symptoms: marked tension, agitation, apprehension, restlessness, hypermotility
- often alleviates anxiety-induced somatic complaints
- frequently helps strengthen emotional resources
- helps the patient maintain realistic contact with environment, closer harmony with family

Thus, when you consider the anxiety moderate to severe... consider Mellaril.

Contraindications: Severely depressed or comatose states from any cause, and in association with or following MAO inhibitors; severe hypertensive or hypotensive heart disease.

Precautions: Hypersensitivity reactions (e.g., leukopenia, agranulocytosis) and convulsive seizures are infrequent. Pigmentary retinopathy has been observed where doses in excess of those recommended were used for long periods of time. May potentiate central nervous system depressants, atropine, and phosphorus insecticides. Where complete mental alertness is required, administer the drug cautiously and increase dosage gradually. In addition, orthostatic hypotension (especially in female patients) has been observed. Epinephrine should be avoided in treatment of drug-induced hypotension.

Side Effects: Pseudoparkinsonism and other extrapyramidal disorders are infrequent; drowsiness, especially in high doses early in treatment, may occur; nocturnal confusion, dryness of the mouth, nasal stuffiness, headache, peripheral edema, lactation, galactorrhea, and inhibition of ejaculation are noted on occasion; photosensitivity and other allergic skin reactions may occur but are extremely rare.

Before prescribing, see package insert for full product information.

Tumor Conference

Hemangiomatosis of the Small Bowel

ALTHOUGH HEMANGIOMAS are frequently found in various areas of the body, they rarely involve the gastrointestinal tract. A review of the literature in 1964 by Dwyer revealed only 200 cases of intestinal hemangiomas reported over a 100-year period.¹ Gentry reviewed 1,400,000 case records at the Mayo Clinic and found only 106 cases of vascular lesions involving the intestine.² Although intestinal hemangiomas frequently bleed, rarely are they considered in the differential diagnosis of gastrointestinal hemorrhage.

Recently we had an occasion to treat a patient with multiple diffuse hemangiomata of the small bowel at the University of Minnesota Hospitals. The purpose of this communication is to present the pertinent clinical features of this case and to briefly discuss the management of multiple diffuse telangiectasia* of the small intestine. Particular emphasis is given to the need for surgical resection of the involved bowel in those patients in whom the disease has resulted in chronic disability or even a threat to their life.

Case Report

A 49-year-old bus driver was admitted to the University of Minnesota Hospitals on June 10, 1966, with a three-day history of rectal bleeding and melena and a falling hemoglobin despite the administration of eight units of whole blood at an outside hospital. His past history revealed that he had had two similar episodes in the past, once in 1963 at which time he required the administration of 10 units of whole blood for painless rectal bleeding. A rather extensive course of investigation in 1963 including an x-ray examination of the upper and lower gastrointestinal tract revealed no apparent cause for gastrointestinal hemorrhage. He had no symptoms suggestive of peptic ulcer disease or esophageal varices. After the initial episode in 1963 he enjoyed a symptom-free interval until March 1965, at which time he again sustained a massive hemorrhage. After the administration of eight units of blood an exploratory laparotomy revealed multiple small hemangiomata involving the entire jejunum. The remaining abdominal organs were normal. A 13-cm. segment of proximal jejunum was resected and histological examination confirmed the presence of capillary telangiectasia.**

He continued to do well until June of 1966 when melena recurred. Each of the three bleeding episodes was heralded by sudden weakness and fainting, a particularly treacherous situation for a bus driver. On arrival at the University of Minnesota Hospitals his hemoglobin measured 7 Gm. %; his blood pressure was 130/70 and pulse 120. Physical examination revealed a well-developed male with no other evident abnormalities except the pronounced anemia and melena. Gastric aspiration revealed no blood although he

*See Test Your Word Score Page 1659.

**The exploratory laparotomy was carried out by Dr. C. M. Phibbs, Jr., at St. Barnabas Hospital, Minneapolis, Minnesota.

was actively bleeding. During the ensuing three days he received 11 units of blood and his hemoglobin stabilized at 13 Gm. %. A selective superior mesenteric and celiac arteriogram revealed no evident abnormalities. Because of the insidious onset of the bleeding episodes and because of the serious consequences in his occupation as a bus driver, the decision to operate upon this man was made in the hope of being able to resect most, if not all, of the involved small intestine.

On June 21, 1966, the patient was taken to the operating room and the abdomen was explored through a midline incision. The stomach, duodenum, and the proximal three inches of jejunum were entirely normal, as was the colon. However, the remainder of the jejunum was studded with multiple small hemangiomas measuring from one to 10 mm. in diameter (Figure 1). After carefully measuring the entire length of the small intestine it was found that the distal eight feet of ileum were free of disease. Except for the most proximal two inches all of the jejunum was resected and a jejunal-ileostomy in a single-layer closed anastomosis was carried out. The patient's postoperative course was entirely uneventful and he was discharged from the hospital on June 27, 1966.

Fig. 1. Intra-operative photograph of small bowel revealing multiple small hemangiomas.

Examination of the removed specimen revealed an eight-foot length of jejunum with multiple hemangiomas, the largest measuring one cm. in diameter, with a small mucosal defect. Microscopic examination of the hemangiomas revealed multiple vascular spaces lined with endothelium; the appearance was consistent with a diagnosis of multiple hemangiomas of the small bowel. The patient was subsequently seen on several occasions in the outpatient department. His only complaint in the early postoperative period was that of three to four loose bowel movements per day, but on his last visit in January of 1967 he stated that he had one formed stool per day. His hemoglobin was 14.2 Gm. % at that time and he had had no recurrence of melena since his operation. The patient again is gainfully employed as a bus driver.

Discussion

Several classifications of vascular lesions involving the gastrointestinal tract have been described, the most common being that proposed by Kaijser, who classified intestinal hemangiomas into four different groups.³

Multiple Phlebectasia

This form of hemangioma usually involves the small bowel, and on microscopic examination large channels are seen which are similar to those seen in the cavernous variety. However, the vascular walls are usually thicker and contain a variable amount of smooth muscle, and the lumen frequently communicates with the sub-mucosal veins. The lesions are nearly always multiple and small and may involve large segments of the intestine. If symptomatic, their presence is usually signified by anemia, melena or painless rectal bleeding.

Cavernous Hemangioma

Cavernous hemangiomata usually involve the large bowel with preference for the sigmoid colon and rectum and may occur either in a diffuse form or in a more circumscribed polypoid variety. Microscopically, the vascular walls do not contain smooth muscles and the histological picture is that of large blood filled spaces lined by round or flat endothelial cells. Though hemorrhage is the most frequent symptom, occasionally they have given rise to large bowel obstruction.

Capillary Hemangioma

This type of hemangioma usually occurs as a single discrete sub-mucosal nodule which at times may become pedunculated. Hemorrhage or intussusception has usually led to a diagnosis of this lesion.

Hemangiomatosis or Multiple Diffuse Telangiectasia

This term implies a manifestation of a widespread disease and on occasion is associated with hemangiomata of the skin and other sites. The clinical setting of this lesion is usually one of long duration before the correct diagnosis is made and is characterized by multiple severe gastrointestinal hemorrhages, anemia, and occasionally even obstruction and intussusception of the bowel. The case presented in this report falls into this group.

Discussion

From a brief review of the literature it would appear that no age group is exempt. In 1966 Nader and Margolin reviewed 48 cases of intestinal hemangiomata in children, including one case of their own.⁴ The average time between the onset of symptoms and the correct diagnosis in their report was 16 years with a range of 0 to 49 years. The bleeding episodes were usually intermittent and sometimes marked by long periods of remission.

The diagnosis of vascular malformation as a cause of gastrointestinal bleeding is largely a diagnosis of exclusion. Intestinal hemangiomatosis has no distinguishing radiological or laboratory features. Occasionally the presence of an extra mucosal filling defect or the presence of phleboliths outside of the pelvis should raise the suspicion of vascular malformation. The diagnosis of intestinal hemangiomatosis may at times be difficult even at operation. Usually the lesions are quite striking when encountered, but may be almost invisible, especially after the bowel has been handled or if active bleeding is present.

As has been stated by Vetto, the tendency for spontaneous remission renders the evaluation of any treatment difficult.⁴ Radiation therapy and injec-

tion of sclerosing agents have not been of any value. In many instances the disease has run a relatively mild course and the administration of blood transfusion and iron have remained the mainstay of treatment. However, in those instances where repeated massive hemorrhages have led to prolonged disability and a threat to life, extensive resection of the involved bowel appears to be justified. Vetto reports four patients who underwent a 50% resection of the small intestine after failure of conservative management.⁵ Two of these patients have had no further evidence of bleeding. In one patient the severity of bleeding had been markedly reduced and in the fourth patient recurrent hemorrhage requiring multiple transfusions occurred.

The patient described in this report has had no further bleeding since his operation, and in view of the serious disability associated with the previous hemorrhages, a 50% resection of the small intestine appears to be fully justified. Since all of the involved small bowel was removed, the likelihood of subsequent recurrence is indeed remote.

Summary

The case of a 49-year-old male with multiple diffuse telangiectasia of the jejunum is presented, who underwent a resection of one half of his small bowel for recurrent life-threatening and disabling hemorrhages. It is suggested that surgical resection of the involved segments of intestine offer the only chance for definitive cure. However, it should be emphasized that large resection should be reserved for those patients whose bleeding is severe and life-threatening.

Bilateral Posterior Lobe Cerebellar Syndrome

Involvement of both posterior lobes of the cerebellum causes dysarthria, marked involvement of gait, and an inability to carry out skilled, voluntary movements on either side. Likely etiologic factors include infections, such as chronic encephalitis, and degenerative or demyelinating lesions, such as multiple sclerosis. Less frequently, tumors may be a cause.

Neurological Conference

Diabetic Neuropathy*

Dr. Steve Drosman:**

The patient is a 24-year-old man complaining of burning and tingling in his legs. He had had symptoms of fatigue, weight loss, polydipsia, and polyuria for about 10 years; however, he did not consult his physician until four and one-half years ago. At that time a diagnosis of diabetes was made and he was started on orinase. Since he failed to improve, he was started on 20 units of protamine zinc insulin. After vacationing for a month, he returned even more fatigued, and his private physician increased his dose of protamine zinc insulin to 40 units. He has remained on this amount for the past four years. During this time the patient did not regulate his diet or attempt to maintain an adequate control of his diabetes.

In April, 1965, the patient had a flu-like episode with high temperature, nausea, vomiting and a great deal of bloating. Chest pain was also present. Upon hospitalization his blood sugar was 675 mg.%. Lente insulin was initially started at 80 units, and eventually reduced to 45 units upon dismissal from the hospital. Towards the latter part of April, 1965, the patient started complaining of burning and cramping pains in his legs and feet. When questioned further about these symptoms, he stated that these pains had been present intermittently for the preceding four years, but neither as severe nor as constant. Increasing neurological symptoms necessitated rehospitalization in June, 1965. Vitamin B-12 therapy was given for 10 days without obvious benefit. His insulin was readjusted at that time to 50 units of lente and 10 units of semilente. In addition he was placed on an 1800 calorie diabetic diet when he was sent home from the hospital. When he left the hospital in June, his normal weight of 150 pounds had decreased and stabilized at 120 pounds, the loss apparently having occurred during the prior six to seven months.

Physical Findings

On physical examination his general appearance was that of a tall, thin young man in no acute distress. The vital signs including blood pressure were normal. Examination of his mouth revealed gingivitis and carious teeth. The heart and lungs appeared to be normal, as was the abdomen. Examination of his extremities showed a reduced muscle tone of the soleus and quadriceps bilaterally, although his strength and coordination appeared normal. The deep tendon reflexes were somewhat sluggish but equal bilaterally. There was a definite hypesthesia and hypalgesia extending from the knees and increasing distally. The cranial nerves were normal. Funduscopic examination revealed no abnormalities of the eye grounds.

Laboratory Studies

The initial lab work revealed a normal complete blood cell count and sedimentation rate, and a 4+ urine sugar and acetone; however, a repeat check noted no urine acetone. The initial blood sugar was 315 mg.%; the serum cholesterol was 220 mg.%; and the serum triglycerides were 165 mg.%, the normal range being 130-135 mg.%. The chest x-ray and electrocardiogram were also within normal limits.

Progress

In diabetic clinic a 2400-calorie low-fat diet was prescribed together with 50 units of lente

*Neurological Conference held November 9, 1965. These conferences are an integral part of the Comprehensive Clinic Program at the University of Minnesota Hospitals.

**Student doctor, University of Minnesota Hospitals.

and 10 units of semilente daily. A neurological evaluation considered the sensory loss to be a peripheral neuritis secondary to diabetes; and thiamine 100 milligrams three times weekly intramuscularly and multivits were recommended. His burning dysesthesias* continued unabated at home, and when he returned to the Neurology Clinic on October 18, 1965, it was felt that he should be admitted for more intensive care.

The Evaluation

Medical Evaluation

Dr. Gerald Lee:**

Poor dental hygiene could be a cause for poor control. The patient has multiple *dental caries*. Secondly, although he does not appear to have an occult hidden infection, when diabetes is not well controlled, an infection should be suspected. I would recommend obtaining repeat chest x-rays with apical lordotic views, and a complete blood count. We are checking the 7 a.m. temperature daily but, as *tuberculosis* characteristically produces an evening temperature, I would favor taking two or three temperatures per day. Williams¹ makes the point that a diabetic patient may develop an *allergic reaction* to beef insulin which may be responsible for nerve damage and hence aggravate or cause diabetic neuropathy.

Future Problems

Although diabetic neuropathy is the patient's main complaint now, we might also consider future problems that will probably arise.

With the advent of insulin, diabetes is a different disease, since patients survive longer to suffer or expire from vascular complications. Williams and others also have recently emphasized that disturbance of fat metabolism is very common among diabetics. Most diabetics have hypercholesterolemia or hypertriglyceridemia or both and thereby premature atherosclerosis. Fatty acid metabolism is now thought to be closely related to the beta chain of insulin. The alpha and beta chains are split as they are being utilized; the beta chain is thought to be a stimulus for fatty acid synthesis. Patients less frequently develop allergic reactions to pork insulin. Since coronary heart disease and peripheral vascular disease are the major problems that confront the diabetic with increasing years, each diabetic should try to reduce known risk factors. Smoking is very harmful. Hypertension should be controlled, and causes for an increase of blood pressure should be established and corrected if possible. Hyperlipemia also should be reduced, if possible, by diet or drug.

Neurological Evaluation

Dr. Robert Soll:†

I would concur with Dr. Lee's statement that diabetes is very commonly complicated by severe arteriosclerosis. Not only is this true of coronary artery disease, but it is likewise true of all the vessels in the body, including the cerebral vessels. In diabetic neuropathy the most important etiological factor is probably an arteriosclerotic involvement of the vasa nervorum of the peripheral nerves, causing an inadequate vascular supply to the nerves, resulting in a *patchy demyelination* as well as loss of the axons themselves. Both motor and sensory conduction may be impaired. In an interesting review in

*See Test Your Word Score Page 1659.

**Medical Fellow Specialist and Instructor, Department of Medicine, University of Minnesota Hospitals.

†Neurologist, University of Minnesota Hospitals.

1957, Spratt and Hardin² noted that about 14% of all diabetics will develop a neuropathy. Neuropathies can involve all peripheral nerves, sensory and motor. Pain sensations are common and usually appear as burning paresthesias. Interestingly, some pains can be lightening-like, simulating those occurring in tabes dorsalis; this is called *diabetic pseudotabes*. Probably the most common peripheral nerve involved is the femoral, but the sciatic, median or ulnar nerve may also be implicated on occasion. A diabetic patient may develop a *foot drop*; frequently this may be associated with leg crossing, implicating pressure on the peroneal nerve. This suggests that a peripheral nerve in a diabetic patient may be more susceptible to trauma; however, some diabetics probably do not cross their legs and still get a foot drop.

Diabetic patients will frequently show an elevation of the cerebrospinal fluid protein, whereas patients who have no neurological symptoms will usually have a normal protein value. In a series of 84 cases of diabetic neuropathy, Bailey and Murray³ found a cerebrospinal fluid protein elevated above 50 mg.% in 73 patients, or approximately an 87% incidence.

Treatment

Treatment of diabetic neuropathy involves the same conservative principles as neuropathies in general: that is, good nursing care, bed rest, and relatively early passive range of motion to prevent contractures. Patients on prolonged bed rest frequently develop tightness in their calf muscles as a result of inactivity. Posterior splints of the lower legs and feet may also be used to support the feet in the correct posture during bed rest. Strict control of the caloric intake, together with very close regulation of insulin dosage, is an absolute necessity.

Very often patients with diabetic neuropathy do not respond well to treatment. There is no good explanation for this, however, since the definite cause of diabetic neuropathy is unknown, though arteriosclerotic changes may be responsible, and hyperglycemia may also be involved. Vitamins have been used to supplement the diet. Thiamine and vitamin B-12 are usually given, although these have not definitely been shown to be of specific help in diabetic neuropathy. Urinary tract infections as well as infections in other areas must be watched for and treated appropriately. Patients with neuropathies are prone to develop decubitus ulcers as well as trophic ulcers of the skin, which can be very painful but can be minimized with good nursing care. Symptomatically, some of the more troublesome problems in treatment of these patients are the burning paresthesias on the bottoms of their feet and the pains in their legs. These can be alleviated by the application of local heat, care being taken, however, not to burn the patient.

Psychological Evaluation

Dr. Manfred Meier:*

General intellectual functioning in this man is at a high average level; his full scale IQ on the Wechsler Adult Intelligence Scale was 116. His verbal IQ was 119, while his performance IQ was 110. This discrepancy of nine points is probably insignificant. In general, the subtest scatter does not support the notion that he has undergone any significant intellectual impairment. In order to confirm this inference, we gave a series of other tests covering a wide range of functions including planning with foresight ability as

*Associate Professor, Department of Neurology, University of Minnesota Hospitals.

measured by the Porteus Maze Test, immediate visual retention as measured by the Benton visual retention test, and the Bender visual-motor gestalt reproduction. Also some additional tests were given such as the Trail Making test and our new experimental measures including visual discrimination at a complex level of visual functioning and readaptation to rotated visual space. Throughout, there was no evidence of intellectual impairment, and therefore, by inference, no indication of organic cerebral dysfunction.

Personality

Personality functioning, however, shows some rather clear-cut abnormal indications on the Minnesota Multiphasic Personality Inventory in the form of deviations in a somatic, neurotic direction. He produces multiple elevations including high scores on the hypochondriasis, hysteria, psychopathic deviate and schizophrenia scale scores. The profile in general follows a downward slope characteristic of the somatic neuroses. There is a high probability that he generates multiple, diffuse, fluctuating somatic complaints which are likely to be referred to the periphery of the body but could include visceral complaints as well. Ordinarily such complaints, if generated on a somatic-neurotic basis, would be expected to help an individual achieve some measure of anxiety reduction or adaptation.

Anxiety

In this patient, secondary elevations on depression and psychasthenia suggest that such an anxiety or discomfort-reducing function has not been fully achieved. As a result we would infer that he has not been able to manage efficiently an anxiety-reducing adjustment on a conversion reaction basis. At this level of analysis one can never rule out organic considerations. In this situation, it can only be inferred that he is presenting evidence of considerable functional overlay. The most alarming aspect of his profile is that such high scores on the somatic neurotic scales are unusual in an individual of this age. Even in older individuals such scores are more often associated with a chronic conversion picture. At his age, I would even consider a vocational incapacitation on a neurotic basis as a potentially negative outcome; therefore I would strongly recommend that efforts be made to mobilize this individual at the earliest time through appropriate rehabilitation channels. Another alternative would be to consider psychotherapy as a treatment to modify what appears to be increasingly more dependent and maladaptive uses of somatization. However, chances are that he would reject psychogenic explanations and actively resist any efforts along these lines. Therefore, the clearest indications of behavioral abnormality in this array of data are the indications in the multiphasic of a chronic, somatic-neurotic adjustment, indications which I think, have implications for the immediate future as far as rehabilitation efforts are concerned. Whether or not he also has extensive medical problems with a clearly organic basis, I would not be surprised to find that some of his symptoms cannot be explained in organic terms. If we did successfully treat a medical condition to reduce certain complaints, one would predict that he would generate new complaints. Also he would probably generate even more dependence upon somatic complaints as a way of handling stress. I am somewhat alarmed by the data in terms of the prognostic implications they carry, and I would urge strongly that efforts be made to mobilize this man towards a more independent and productive kind of vocational and

APPETITE
SUPPRESSANTS.

AN IMPORTANT FACTOR
IN LONG-TERM THERAPY!

CONTROL FOOD AND MOOD ALL DAY LONG WITH A SINGLE MORNING DOSE

One Ambar Extentab before breakfast can help control most patients' appetite for up to 12 hours. Methamphetamine, the appetite suppressant, gently elevates mood and helps overcome dieting frustrations. Phenobarbital, the sedative in Ambar, controls irritability and anxiety...helps maintain a state of mental calm and equanimity. Both work together to ease the tensions that erode the willpower during periods of dieting. Also available: Ambar #1 Extentabs®—methamphetamine hydrochloride 10 mg., phenobarbital 64.8 mg. (1 gr.) (Warning: may be habit forming).

AMBAR #2 EXTENTABS®

methamphetamine HCl 15 mg.,
phenobarbital 64.8 mg. (1 gr.)
(Warning: may be habit forming).

BRIEF SUMMARY/Indications: Ambar suppresses appetite and helps offset emotional reactions to dieting. **Contraindications:** Hypersensitivity to barbiturates or sympathomimetics; patients with advanced renal or hepatic disease. **Precautions:** Administer with caution in the presence of cardiovascular disease or hypertension. **Side Effects:** Nervousness or excitement occasionally noted, but usually infrequent at recommended dosages. Slight drowsiness has been reported rarely. See package insert for further details.

(COMPLIMENTS OF
DIMETAPP)

Help clear up that miserable stuffed-up feeling with Dimetapp. Each hard-working Extentab brings welcome relief from the stuffiness, drip and congestion of upper respiratory conditions for up to 10-12 hours. Yet, patients seldom experience drowsiness or overstimulation. The key to success is the Dimetapp formula: Dimetane (brompheniramine maleate)—along with phenylephrine and phenylpropanolamine, two time-tested decongestants. They get the job done... in a hurry.

Indications: Dimetapp is indicated for symptomatic relief of the allergic manifestations of respiratory illnesses, such as the common cold and bronchial asthma, seasonal allergies, sinusitis, rhinitis, conjunctivitis, and otitis.

Contraindications: Hypersensitivity to antihistamines. Not recommended for use during pregnancy.

Precautions: Until patient's response has been determined, he should be cautioned against engaging in operations requiring alertness. Administer with care

to patients with cardiac or peripheral vascular diseases or hypertension.

Side Effects: Hypersensitivity reactions including skin rashes, urticaria, hypotension and thrombocytopenia, have been reported on rare occasions. Drowsiness, lassitude, nausea, giddiness, dryness of the mouth, mydriasis, increased irritability or excitement may be encountered.

Dosage: 1 Extentab morning and evening.

Supplied: Bottles of 100 and 500.

interpersonal adjustment. I realize that this is a big order, considering the excessive extent to which he depends on somatic complaints, perhaps generating many of these to avoid work situations and other unpleasant interpersonal situations. In this instance, such mobilization may well become one of the more central aspects of any treatment program.

Social Evaluation

Miss Annie Laurie Baker:*

This interpretation is very interesting in respect to the social situation in which the patient now finds himself. He is a person with an easy, outgoing disposition. He speaks rather freely and is quite happy here.

Family Status

The patient comes from an interesting family. His father was a high school graduate and intended to enter law school; subsequently he spent two years at the University and then joined the police force. For some odd reason he is now a bartender. The patient is the oldest child in a family of five and the only boy. According to his wife, he has been very fond of his little sisters, but there seems to have been considerable rivalry. His mother is apparently a careless sort of person who paid very little attention to his medical problem when it arose.

The patient attended high school but did not graduate. I think it is very interesting that when he was beginning to have a hard time financially last March, he signed up for a correspondence course to finish high school. This cost him \$95 and he is still behind on those payments. Why he quit school is difficult to explain, particularly since he was within seven or eight credits of finishing. He was married at an early age. His wife, also not a high school graduate, is a very pleasant person. Their oldest child is now four. They have a second child 18 months of age, and their third child is expected in January.

Work Habits

Both the patient and his wife state that he has been a very hard worker. He has enjoyed salesmanship and been rather successful at it, although I notice that his work history reveals that he has had a great number of jobs in the past five years. In fact, in the short time they have been married (five years), they have had ten different addresses, purchased two homes and lost both of them. So there is more instability than you would expect to find in so young a person. His wife comes from a well-to-do family in which there are nine children; nevertheless, her father is paying on a \$3500 loan for the patient which amounts to \$144 a month. The patient and his family are now on village relief and have made application for Aid to Dependent Children. If this patient were going to be incapacitated for a period of two to three months, he would have to have some extra assistance, such as Aid to Disabled, which might only augment those tendencies brought out on the psychological report. While he is disabled he will be relieved of responsibility for himself and for his family. This will certainly interfere with his motivation. Even without assistance, he is largely dependent on his father-in-law. He says he has been a successful salesman, and his wife admits that he is an exceedingly hard worker. When he does work he puts in 16 hours a day; however, he has been ill much of the time. His last employment was selling appliances. He is

*Director Social Service Department, University of Minnesota Hospitals.

not concerned much about what he will do when he leaves here. Likewise, he seems to have little concern for his family; in the past when he has had trouble, he has simply gone home. His family has taken him in and never inquired about his wife. She expects her own family to help her out. So we have a young couple, soon to have their third child; he is 24 and she 22, with their whole future before them.

Vocational Rehabilitation Evaluation

Mr. Fred Borden:*

Dr. Meier has related the results of the Wechsler Adult Intelligence Scale test placing the patient in the high average ability range. During vocational counseling in the rehabilitation center we have observed him during the last week and have administered additional tests which would confirm the estimate of his general mental ability. On the other hand we have some other information which does not quite fit this picture.

Aptitude Tests

The State of Minnesota has a uniform testing procedure whereby each high school junior in the state is tested. This man was a junior in 1959 and his high school rank at that time was in the bottom 5% of the class. Further information includes the results of an achievement test, the Minnesota Scholastic Aptitude test which, with a high loading of word usage, is a good predictor of how a student might do in college and also necessarily reflects what he has learned in high school. In this test our patient scored better than just about 20 per cent of the high school juniors in Minnesota. A Co-op English test, which he also took at this time and which should reflect what he has learned in high school, also ranks him above 20 per cent of the Minnesota high school population. These measures of achievement are definitely not consistent with the measure of his intellectual ability we have obtained. We would expect that in a high school group he should rank probably around the seventy-fifth percentile if he were fully using his intellectual potential. I feel that the picture given to us by this data indicates that this patient under-achieved in high school, and this should help us understand why he dropped out. My information is that he left high school in his senior year, then tried to go back but got too slow a start and again quit. He began to work for the remainder of that year and transferred to another high school the next year. Following the same pattern as before, he dropped out during the first semester. School was not a satisfying experience for him. In discussing this, he commented, "Whenever I tried to study I just would think about all the fun my buddies were having and I'd have to get out and bounce around." He said that about 80% of his buddies were high school drop-outs. Thus the picture of his past high school academic achievement appears rather glib.

Vocational Aptitude

We have other information on more specific vocational aptitudes which is not nearly as discouraging. We gave him the battery of specific aptitude tests which are generally used in U. S. Employment Services, designed to measure specific aptitudes isolated from the general concept of intelligence. On none of these eight-part tests did he score significantly below average and, in two

*Vocational Counselor, Physical Medicine and Rehabilitation Department, University of Minnesota Hospitals.

areas, the results were quite good. For instance, he showed spatial ability in the strong average range; and his ability for clerical perception, which consists of rapid checking in order to identify errors or differences in written materials, would have to be considered above average—probably in the top 10% of the general population. He has taken two interest tests, the results of one of which are now available, showing an interest pattern consistent with his sales background, i.e., persuasive interest. These results are co-existent also with interest in the clerical computational area. In discussing his vocational plans, he says, "Well, this really is dependent on what the doctors tell me when I leave." This was his first reaction to my efforts to get him started thinking about his future in terms of jobs; he didn't feel that he could make any definite plans. On a second interview he said that one thing that interests him is drafting, also that he loves saleswork; which is consistent with his tested interest patterns. At the same time, he feels that control of his medical condition will probably necessitate at least an alteration in his selling job or perhaps a complete withdrawal from the selling area because of the lack of a routine schedule that often goes with it. I would suggest, in terms of his measured ability and aptitude, that the picture does not seem at all bleak from our standpoint; on the other hand, I have seen the results which Dr. Meier referred to in the multiphasic. My conclusion is that we should take all the immediate action we can to facilitate his contact with the world of work and with reality in general. I would be very much distressed to see him in a period of long passive convalescence. The desirable thing would be to get him active before this pattern becomes permanent.

What are the things that might be done from the vocational standpoint? Aside from the rather bleak prognosis psychologically, I would say that he has many good job assets, but I am a little disturbed about two conflicting pieces of data. Possibly Dr. Meier would comment on the elevation in scales one and three on the multiphasic, contrasting with the fact that he has been working 16 hours a day for a period of about a year, and also with the fact that he has had two selling jobs in which he was working from 8 a.m. to 10 p.m., six days a week. Specifically, I think that the Division of Vocational Rehabilitation of the State of Minnesota would be very willing to accept this man as a potential vocational rehabilitation case and might offer some kind of training program. An immediate consideration is: how can this man earn a high school diploma? One way would be to take the high school General Education Development test and be awarded a diploma by one of the high schools he attended. Also referral to the Division of Vocational Rehabilitation would be entirely appropriate in this case. I would like to continue to see him further, and when he leaves the hospital, I could make a referral to the Division of Vocational Rehabilitation.

Dr. Meier:

I did not want to imply that on the basis of something like the multiphasic alone, the prognosis should be considered bleak. I think there are a number of things working in this patient's favor: first, his substantial level of ability and secondly, his age. What alarmed me was the fact that profiles of this kind are unusual at this age level. Such a finding at this early age should serve to alert us to his present pattern of adjustment which, if allowed to become chronic, may definitely have negative implications from vocational and interpersonal standpoints. I do not know what the prognosis for a suc-

cessful work adjustment is for this case. I don't like what I see in the multiphasic, and if you press me to try to set a probability for his return to a successful work adjustment, assuming that he is already functioning at that level I could not do so. However, I think that his underachievement in high school is consistent with the multiphasic, as underachievement is typically associated with some personality disturbance, although there is no unitary personality disturbance that leads to underachievement. Ordinarily, in high school, underachievement is associated with character defects. In relation to the other things said about the multiphasic, I should have mentioned that there is evidence in this patient's profile of some character defects, in that he does not have a purely somatic neurotic code type. Rather, such features are probably intertwined with some passive aggressive traits, such as a tendency to manipulate and exploit others, poor judgment, and active avoidance of responsibility.

Dr. Soll:

I think this brings out very well the fact that illness carries with it innumerable problems above and beyond the medical ones. If we, as doctors, have the role of helping a patient return to a functioning level in society, we have a great task set out for us here. It is not simply a matter of controlling the diet and insulin.

The Following Recommendations Can Be Summarized:

1. Infectious processes should be frequently looked for by periodic checks of the patient's temperature, white blood cell count, chest x-rays, and dental examinations.
2. Strict control of the diabetes should be maintained through an adequate diet and precise regulation of the patient's insulin requirements.
3. Psychotherapy should be considered for the purpose of increasing the patient's understanding of his own problems as well as those of his family.
4. Vocational rehabilitation counseling should be continued with the ultimate aim of obtaining employment that will be compatible with the patient's physical and mental condition.
5. Financial support should be provided through Aid to Dependent Children until the patient becomes adequately self supporting.

Clinical Path Conference

Respirator Lung Syndrome

Robert L. Strom, M.D.:*

A 35-year-old white housewife was hospitalized with a complaint of left flank pain of three days' duration. The pain was described as steady with some radiation to the left inguinal region. Fever and chills were noted on the day of admission.

Diabetes mellitus had been present for 30 years. An insulin dosage of 37 units nph had been maintained; however, increased glycosuria had been present for the past week. The patient had been hospitalized on nine previous occasions for pyelonephritis over a 20-year period.

On examination, the blood pressure was 100/70, the pulse 90 per minute, the temperature 102.2°F., and the respirations 24 per minute. The patient was pleasant and cooperative and did not appear ill. Some tenderness was elicited in the left costophrenic angle.

On the evening of the first hospital day, intravenous 50% dextrose was required to maintain the blood sugar above 50 mg.%. A chest X ray was interpreted as normal. A flat plate of the abdomen showed a large ureteral stone at the left ureterocystic junction. An emergency intravenous pyelogram showed nonfunction of the left kidney and some hydro-nephrosis on the right. Treatment consisted of intravenous fluids, Colymycin and nasogastric suction. Intermittent doses of Aramine were required to maintain a systolic blood pressure greater than 90 mm. of mercury.

On the second hospital day, a left nephrectomy and partial ureterectomy was performed. During induction of anesthesia, the systolic blood pressure fell to sixty mm. of mercury but responded to intravenous fluids and a reduction of the amount of Halophane administered.

After surgery, the patient remained in the post-anesthetic recovery room for the first two postoperative days because of weak and inadequate respirations. She was totally dependent upon a Bird Mark 7 respirator and a nasotracheal tube. On the first postoperative day, she developed signs of congestive heart failure and was digitalized. Several attempts to stop respiratory assistance resulted in hypoventilation and cyanosis. A chest X ray showed bilateral symmetrical consolidation of the mid- and lower lung fields. On the second postoperative day, a tracheotomy was performed. A blood culture grew out *Proteus* species and the antibiotic therapy was changed to intravenous Keflin.

On the third postoperative day, the patient developed marked dyspnea and cyanosis. The lungs revealed diffuse small rales and scattered wheezes. An electrocardiogram showed an acute right ventricular strain pattern. Right calf tenderness was present but there was no edema of the extremities. Heparin and dextran were administered because of suspected thrombophlebitis. A urine culture grew out *Proteus* species. Thereafter, the patient's condition remained unchanged, although respiratory assistance continued to be necessary.

On the sixth postoperative day, regular insulin was given because of moderate diabetic acidosis. A few hours later, cardiac arrest occurred during tracheal suction, and resuscitation attempts were unsuccessful. Vital signs, intake and output, and laboratory data during hospitalization are listed in Table I.

*Associate Pathologist, Hennepin County General Hospital

Clinical Discussion

Dr. Thomas Mulrooney:*

This young diabetic woman's presenting symptoms strongly suggested a renal stone and recurrent pyelonephritis. Her insulin requirements of 37 units of NpH per day is not unusual for a juvenile diabetic. Apparently, her initial chest X ray was normal. She was alert and cooperative with only mild left costovertebral angle tenderness. On the evening of her first hospital day, 50% dextrose had to be given intravenously in order to keep her blood sugar over 50 mg.%. This disturbed me considerably at first until Dr. Gerald Onstad explained that the lady had received regular insulin earlier in the day and apparently had not been eating adequately. The observed hypotension was apparently due to gram-negative sepsis since we have later laboratory confirmation of *Proteus* organisms in the blood. On the second hospital day, she underwent a left nephrectomy and partial ureterectomy.

Then we come to the first part of her course that is peculiar. She remained in the postoperative recovery room for the first two post-surgical days because of weak, inadequate respirations. During this time, she was totally dependent on a Bird respirator and a nasotracheal tube. In addition, she developed signs of congestive heart failure and was digitalized. Subsequently, all attempts to stop respiratory assistance failed since she promptly developed hypoventilation and cyanosis. Somewhere about this time, she had a tracheotomy. This was probably done since a nasotracheal tube cannot be left in place longer than 48 hours because of danger of erosion of the vocal cords. On the third postoperative day, she developed marked dyspnea associated with a right ventricular strain pattern on her electrocardiogram. With the presence of right-calf tenderness, it is not surprising that it was felt that she was developing pulmonary emboli.

*Attending physician, Department of Internal Medicine, Hennepin County General Hospital.

Tracheal Suction and Sudden Death

On the sixth hospital day, during tracheal suction, a cardiac arrest occurred and all resuscitation attempts were unsuccessful. Sudden death is a potential hazard of tracheal suction. During the time the patient is suctioned, the oxygen source over the tracheal tube has to be removed and when suction is applied over the airway, the patient abruptly becomes very severely hypoxic. Investigators have made measurements with an ear oximeter during tracheal suction and have demonstrated a dramatic fall in oxygen tension during suction. For this reason, we recommend that when tracheal suction is carried out, each suction attempt be kept to a very short period of not over 10 to 15 seconds. Then the oxygen source can be replaced over the trachea and the patient can be ventilated once again prior to the next suction attempt. It seems likely that even with these precautions this patient became sufficiently hypoxic to suffer a cardiac arrest. The reason she became so severely hypoxic, however, is part of the primary lung problem which eventually led to her death. Now I wonder if we could review the X rays with Dr. Tsai?

Dr. S. H. Tsai:*

In reviewing this diabetic lady's films, we discovered that she had quite extensive papillary necrosis on her intravenous pyelogram as early as 1953, twelve years prior to admission. This is not the fatal fulminating course of papillary necrosis, but early deformities in the papillae were present in the left kidney and also to some extent in the right kidney. The initial chest X ray on this admission was within normal limits (Figure 1). On the chest

*Chief, Department of Radiology, Hennepin County General Hospital.

Fig. 1—Normal admission chest roentgenogram.

film taken on the first postoperative day, a small pneumothorax is seen on the left side and there are extensive infiltrations in both lung fields. By the second postoperative day, she has a more extensive alveolar infiltration which is more or less symmetrical (Figure 2). Between the second and third days there is further progression and, thereafter, the chest findings remain unchanged. The X-ray interpretation at that time was diffuse pulmonary edema. In making the diagnosis, we realized that the cardiac silhouette was not enlarged and there was very little change over several days' observation. This is somewhat unusual for pulmonary edema; most often the infiltration shifts and varies from one day to another rather than remaining totally confluent.

Fig. 2—Dense bilateral alveolar infiltration occurring postoperatively.

Dr. Mulrooney:

The part of this lady's course which is unusual and holds our major interest is the difficulty encountered in weaning her off the mechanical respirator. On the third postoperative day, she developed further respiratory difficulty and the possibility of pulmonary emboli was entertained. One could hardly refute this diagnosis.

Blood Gas Measurements

On the fourth hospital day, the arterial blood gas measurements were made, and I might now call your attention to Table 1 of the protocol. The first thing to notice is that the patient was somewhat tachypneic when she entered the hospital, but her respiratory rate progressively rose and by the fourth hospital day was 40 per minute. On the sixth postoperative day, the arterial

b.i.d.

The sensible schedule that covers the patient day and night

If your objective in the use of a broad-spectrum antibiotic is prolonged action, with high blood levels, then you know why b.i.d. DECLOMYCIN is considered to be a sensible dosage schedule.

The maintenance dosage of DECLOMYCIN can be kept at this convenient schedule because of its unusually high effective blood and tissue levels.

The b.i.d. dosage of DECLOMYCIN gives you the comfortable assurance that the patient is well-covered, *day and night*.

In clinical practice, blood levels produced by a therapeutic dose of DECLOMYCIN are high, prolonged, and effective; because of high serum binding and slow renal clearance. And if there's a broader susceptibility pattern of organisms, we've yet to see it.

There is no need to give higher daily dosage than 300 mg b.i.d., except in venereal diseases and Eaton Agent pneumonia.

DECLOMYCIN[®]
DEMETHYLCHLORTETRACYCLINE

Lederle

Prescribing information on next page.

b.i.d. The sensible schedule that covers the patient day and night

DECLOMYCIN Demethylchlortetracycline should be equally or more effective therapeutically than other tetracyclines when the offending organisms are tetracycline-sensitive.

Contraindication: History of hypersensitivity to demethylchlortetracycline.

Warning—In renal impairment, usual doses may lead to excessive accumulation and liver toxicity. Under such conditions, lower than usual doses are indicated, and, if therapy is prolonged, serum level determinations may be advisable. A photodynamic reaction to natural or artificial sunlight has been observed. Small amounts of drug and short exposure may produce an exaggerated sunburn reaction which may range from erythema to severe skin manifestations. In a smaller proportion, photoallergic reactions have been reported. Patients should avoid direct exposure to sunlight and discontinue drug at the first evidence of skin discomfort. Necessary subsequent courses of treatment with tetracyclines should be carefully observed.

Precautions—Overgrowth of nonsusceptible organisms may occur. Constant observation is essential. If new infections appear, appropriate measures should be taken. In infants, increased intracranial pressure with bulging fontanels has been observed. All signs and symptoms have disappeared rapidly upon cessation of treatment.

Side Effects—Gastrointestinal system—anorexia, nausea, vomiting, diarrhea, stomatitis, glossitis, enterocolitis, pruritus ani. Skin—maculopapular and erythematous rashes. A rare case of exfoliative dermatitis has been reported. Photosensitivity; onycholysis and discoloration of the nails (rare). Kidney—rise in BUN, apparently dose related. Transient increase in urinary output, sometimes accompanied by thirst (rare). Hypersensitivity reactions—urticaria, angioneurotic edema, anaphylaxis. Teeth—dental staining (yellow-brown) in children of mothers given this drug during the latter half of pregnancy, and in children given the drug during the neonatal period, infancy and early childhood. Enamel hypoplasia has been seen in a few children. If adverse reaction or idiosyncrasy occurs discontinue medication and institute appropriate therapy.

Average Adult Daily Dosage: 150 mg q.i.d. or 300 mg b.i.d. Should be given 1 hour before or 2 hours after meals, since absorption is impaired by the concomitant administration of high calcium content drugs, foods and some dairy products. Treatment of streptococcal infections should continue for 10 days, even though symptoms have subsided.

In the treatment of syphilis a dosage schedule of a total of 12 to 18 Gm. given in equally divided doses over a period of 10 to 15 days should be followed. Close follow-up observation of the patient is recommended, including appropriate laboratory tests, since demethylchlortetracycline has not had adequate evaluation in all stages of syphilis. Spinal fluid examination should be included as part of this follow-up.

Acute gonococcal anterior urethritis in males has been treated effectively with a single dose of 600-900 mg. of DECLOMYCIN Demethylchlortetracycline. Individuals unable to tolerate large single doses due to gastrointestinal side effects may be treated with 150 mg. every 6 hours for a minimum of 4 doses or 300 mg. every 12 hours for a minimum of 2 doses. Females should be treated with a dosage of 150 mg. every 6 hours or 300 mg. every 12 hours until a cure is effected.

Primary Atypical Pneumonia (Eaton Agent): The average adult daily dosage is 900 mg. in 3 divided doses for six days.

LEDERLE LABORATORIES, A Division of
American Cyanamid Company, Pearl River, N.Y.

blood gas studies were strikingly abnormal, particularly if they were drawn while the patient was on the respirator. I direct your attention to the PO_2 of 40 and the pCO_2 of 46 mm. of mercury. The normal CO_2 tension in blood is 40 mm. of mercury with a little room for variation, but 46 mm. of mercury is definitely elevated. It is not an extreme elevation, but it means that this patient, at that particular time, was having difficulty eliminating CO_2 . Even more dramatic is the PO_2 of 40 while the patient is on a respirator. The normal PO_2 when one breathes room air is 90 mm. of mercury. A patient who is on a respirator is inhaling enriched oxygen concentrations, and the alveolar oxygen tension may be several hundred millimeters of mercury, depending upon how the respirator is set up and what concentration of oxygen is being used. The difference then between the oxygen tension in the alveolar air and the oxygen tension in the arterial blood of this patient must have been enormous. This represents a major shunt; for some reason, large amounts of blood were bypassing the ventilated portions of the lung.

What we have to discuss then in this patient is what sort of problem caused us to be unable to remove her from a respirator. Why should a person develop persistent hypoventilation after the respirator is removed?

Chronic Lung Disease

The first thing one thinks of is the presence of chronic lung disease. In patients with obstructive emphysema and severe underlying chronic pulmonary disease, when we attempt to remove the respirator the patient is unable to ventilate for himself sufficiently. One must consider depression of the respiratory center by the administration of oxygen. This situation almost invariably occurs in patients who before oxygen was administered were seriously hypoventilated and had high concentrations of arterial CO_2 . Under these conditions, the respiratory center is depressed by the continuous excessive amount of CO_2 present. We assume that the low oxygen tension acts as a stimulus to respiration and when we relieve this by administering oxygen the patient gets into trouble. We can readily dismiss this in the patient under discussion since the initial chest X ray was perfectly normal and there was nothing in the history or physical examination which would suggest chronic lung disease. We evidently started out with a patient with normal lungs.

Central Nervous System Disease

A massive cerebral vascular accident such as a sudden destructive lesion of the brain stem can cause such a respiratory disturbance. Nothing in the protocol suggests this patient developed any other neurologic abnormalities; so this seems highly unlikely.

Diseases of the Chest Wall

Leaving the nervous system, one could think of diseases that affect the chest wall or its innervation and make it impossible for the patient to ventilate normally. Examples of these abnormalities would be a patient who has a traumatic flail chest or some restrictive disease of the chest wall such as kyphoscoliosis or rheumatoid spondylitis. A patient who has poliomyelitis may fall into this category, but none of these conditions appear to apply to our patient.

Neuromuscular Paralysis

We might consider some weakness of the respiratory muscles due to a toxin or poison such as in tetanus, hypokalemic paralysis, or an inherited deficiency of the enzyme pseudocholinesterase. In the general population there are a few people who do not have a normal amount of pseudocholinesterase and are discovered following surgical anesthesia. There have now been some case reports of difficulties encountered with patients who were given succinyl choline, an agent which paralyzes the muscles and is usually destroyed in about three or four minutes by pseudocholinesterase. When given to these patients, the succinyl choline is not destroyed for hours and hours and the patients require prolonged respiratory assistance. As nearly as I can determine, in this syndrome the entire duration of the problem is not longer than four or five hours and succinyl choline paralysis seems quite unlikely in our patient.

So we are finally left with the problem of a patient who was able to breathe normally prior to her surgery but never afterward, and we are forced to conclude that some sort of change in her lung developed during the time that she was on the respirator. This conclusion is certainly strengthened by the X rays, with their progression from a normal chest to a grossly abnormal picture (Figure 2).

Pulmonary Edema

One of the diagnostic possibilities that was raised was pulmonary edema, and I think that in a sense she did have pulmonary edema although not from left-sided heart failure which we usually consider to be the cause of that state. Her heart was not enlarged and digitalization and positive pressure breathing did not alter the picture.

Pneumonia

Another possibility we would have to consider is that she may have developed a massive infection in the lung, presumably due to *Proteus* organisms. I guess we cannot entirely exclude that event, but she failed to respond to antibiotics and the infiltration remained unchanged.

Insufficient Inflation of the Lung

That leaves us with two different possibilities that can occur to individuals who are ventilated with respirators. These two conditions may be related to each other. The first one I want to mention is the effect of insufficient inflation of the lung. As you are well aware, everyone sighs from time to time (women perhaps more often than men). Each individual takes a deep breath on the average of four or five times an hour. It has been demonstrated in animals and human beings that this sighing serves a very useful purpose. In fact, if an animal or human being is ventilated with a constant tidal volume and is not permitted to sigh, he will get into respiratory difficulty. This difficulty is manifested by a progressive fall in the arterial oxygen tension and a progressive decrease in the pulmonary compliance or distensibility of the lung. A physiologist in Boston, Jere Meade, first demonstrated this in dogs, and he interpreted the data to indicate the development of progressive microatelectasis.¹ In a normal lung, when expiration occurs, some of the small air

spaces collapse, but expand again with the next breath. His contention was that some of them did not re-expand and were only expanded when a deeper breath or sigh occurred. Bendixon, who is in charge of a large respiratory unit in Boston, made some physiological measurements in anesthetized human beings to demonstrate this same phenomenon.^{2,3}

This might have occurred with our patient and demonstrates that when anyone is put on continuous artificial ventilation, the attending physician should instruct personnel to see to it that the patient takes at least one deep inspiration every 15 minutes. This can be done in an unconscious patient simply by increasing the pressure on the respirator. Otherwise, the arterial oxygen tension will progressively fall even though the patient is being ventilated with 100% oxygen. Eventually, the amount of pressure required to inflate the lungs will rise even to a point that cannot be achieved.

Respirator Lung Syndrome

The other problem that can occur with people on respirators has been called "respirator lung syndrome" and may be a manifestation of oxygen toxicity. Recently, Cederberg in Sweden and Nash in Boston have reported pathological changes in patients who are ventilated with high oxygen concentrations over a prolonged period of time.^{4,5} Nash compared the lungs of 70 respirator patients who died in a respiratory care unit with the lungs of 70 other people who died elsewhere in the same hospital. Both the controls and the respirator patients had some findings in common, such as bronchopneumonia, pulmonary infarction, pulmonary edema and congestion. However, there were some pathologic changes that were confined almost exclusively to patients who had been on a respirator. In those who died rather early this consisted primarily of edema of the alveolar septae with hyaline membranes similar to membranes seen in respiratory distress syndrome of the newborn. Those patients who died after a longer period on the respirator showed a proliferative response in the alveolar septae.

These investigators attempted to correlate these pathological changes with what had been done to the patients during life. They divided the patients into four groups. Group I included those who had received positive pressure for less than ten days with relatively low concentrations of oxygen (40 to 90%). Group II were those who received respiratory assistance for greater than ten days with the same low concentration of oxygen. Group III were those who received assistance for less than ten days but inhaled 100% oxygen. Group IV were ventilated for greater than ten days with 100% oxygen. In brief, they found that the pathological alterations increased the longer the patients were on the respirator and with higher concentrations of oxygen inhaled. They also found that if they ignored the oxygen concentration and just compared the changes on the basis of time on the respirator, there was no difference in the two groups. It was their opinion that the damage resulted from the oxygen administration.

Oxygen Toxicity

These workers pointed out something that startled me. The oxygen concentration delivered by the commonly used positive pressure respirator when the main stream nebulizer is running (and this is the usual mode of operation) is about 90%. This was surprising because the literature that comes with the machines states that when the machines are set for "air mix" they deliver an

oxygen concentration of about 40%. I always thought this was true and never measured it. In a sense, it is true, but the problem is that the machines in practice are always set up with a heated nebulizer powered with 100% oxygen. What the patient breathes is a mixture of air coming out of the machine and 100% oxygen coming out of the nebulizer resulting in an inhaled oxygen concentration of about 90%.

It has been demonstrated in the past that oxygen in high concentration is toxic to both animals and man. Dogs who breathe 100% oxygen at atmospheric pressure die in about three days, and human beings who breathe 100% oxygen at atmospheric pressure develop symptoms of chest pain, cough and diminished pulmonary compliance which are thought to be at least partly due to oxygen. In any event, there is accumulating evidence that high oxygen tensions could be potentially toxic when given for a long period of time.

It should be said at the same time, however, that these high oxygen tensions may be necessary. It is certainly apparent that this lady could not have survived without the high oxygen tension since her arterial PO_2 was only 40 mm. of mercury, barely enough to sustain life. I certainly do not want to leave the impression that cyanotic patients should not be given oxygen because it might hurt them. This appears to be a threat that we must accept at present, and hopefully we may find some solution for it.

My conclusion then would be that the cause of death in this patient was progressive respiratory failure secondary to the use of a mechanical respirator with relatively high oxygen tension and that in addition she had diabetes mellitus, pyelonephritis, and acute *Proteus* septicemia.

Clinical Diagnosis:

1. Respirator lung syndrome with oxygen toxicity and hyaline membrane disease.
2. Diabetes mellitus.
3. Ureteral lithiasis and acute pyelonephritis.
4. Septicemia due to *Proteus* species.

Pathological Findings

Dr. Robert L. Strom:*

The autopsy findings in this lady involved many systems, and I will take up last the findings in the lungs which hold the major interest. The pleural cavities contained 500 and 700 cc. respectively of pink-colored fluid.

Bacterial Endocarditis

The total heart weight was only 300 grams and the heart appeared normal to external examination. When the heart was opened the valves were examined and multiple vegetations were seen on the aortic and tricuspid valves. The aortic valve was not perforated due to the infection, but one can see a jet lesion on the intima of the aorta above the valve in Figure 3. This represents good evidence of acute bacterial endocarditis since *Proteus* septicemia occurred during life. When we examined the tricuspid valve we again found evidence of right-sided bacterial vegetations with several of the valve leaflets being involved (Figure 4). The vegetations were made up primarily of layered platelets with many neutrophils and histiocytes confirming an infectious etiology. The absence of stainable organisms is not surprising since the patient was on Keflin and this antibiotic is known to be highly effective against

*Associate Pathologist, Hennepin County General Hospital.

Proteus species. The patient had evidence of diffuse embolic phenomena involving the brain, spleen and kidney.

Fig. 3—Heart showing acute bacterial endocarditis of aortic valve. Jet lesions are noted on the intima of the aorta and on the aortic leaf of the mitral valve.

Fig. 4—Tricuspid valve with verrucous vegetation from right-sided acute bacterial endocarditis.

Fig. 5—Renal glomerulus showing nodular glomerulosclerosis of Kimmelstiel Wilson $\times 400$.

Renal Findings

A number of findings were observed in the lower urinary tract. There was a large calculus in the left ureter and the left kidney had been removed. The right kidney was not obstructed by a ureteral calculus, but it did show some papillary necrosis and evidence of acute pyelonephritis. It also showed thinning of the renal cortex down to about 3 mm., suggesting chronic renal disease with superimposed pyelonephritis. A few small microabscesses

were seen in the renal substance, and the glomeruli showed changes of a nodular type characteristic of Kimmelstiel-Wilson's disease (Figure 5). Several glomeruli in the kidney showed evidence of focal embolic nephritis with infarction of portions of the glomerulus and infiltrations of neutrophils (Figure 6). Therefore, we feel the kidney was the source of the *Proteus* septicemia, which may have resulted in the infection of a normal aortic and tricuspid valve.

Fig. 6—Focal infarction of renal glomerulus by a bacterial embolus $\times 100$.

Oxygen Alveolopathy

The lung findings were extremely interesting. The lung weights were 1100 and 1150 grams respectively, making a combined weight of 2250 grams. In the studies of Nash, the combined lung weights in histories of 70 patients nearly all exceeded 1800 grams. A striking thing about these lungs is that they stand up firmly and do not collapse as a normal lung would when you place it on a table. The cut surface of the lung is fleshy and meaty, and as we cut into the lung, no fluid comes forth from the cut surface (Figure 7). A small hemorrhagic pulmonary infarction is present at the left apex of the lung.

Fig. 7—Heavy gross lung with fleshy fibrinous cut surface.

Histologic sections of the lung confirm the clinical impression of oxygen toxicity. Nash divided the pathologic response into two phases. The initial phase was termed exudative and consisted of disruption of alveolar capillaries with hemorrhage into alveolar spaces, edema of the interalveolar septae and development of a fibrin membrane. The second or proliferative phase was characterized by a fibroblastic reaction with resulting thickening of the

alveolar septae. In Figure 8 we see well-developed alveolar membranes which tend to line the alveolar spaces. In addition, one can see increased macrophage activity. It has been felt that the alveolar macrophages may be inactivated by oxygen since they produce surfactant, a lipoprotein which tends to restore the normal amount of lubrication to the alveoli so that they can open up and be aerated.

Fig. 8—Fibrin membrane surrounding alveolar with increased macrophage activity $\times 400$.

With the Bird Mark 7 and the Bennett PR 1 respirator, the nebulizer flow rate may be 6 to 8 liters per minute, and with the use of oxygen to power the nebulizer, the air mixture delivered contains 93% oxygen. With compressed air used to power the nebulizer, the air mixture contains 60% oxygen. In this institution we use a Bird Mark 7 respirator routinely. Since the pathologic findings described by Nash correlated well with the high oxygen tension but did not correlate with the length of time on the respirator, we may be dealing with a misnomer. The disease state in the lung should not in the strictest sense be interpreted as a respirator lung but rather an oxygen alveolopathy. It has been proposed that the inspired oxygen concentration of respirator patients be monitored and that high oxygen tensions be lowered as soon as feasible.

Pathological Diagnosis

1. Respirator lung syndrome (oxygen alveolopathy with fibrin membranes of the lung).
2. Diabetes mellitus (clinical).
3. Ureterolithiasis with acute pyelonephritis and *Proteus* septicemia.
4. Acute bacterial endocarditis of the aortic and tricuspid valve with systemic embolization.
5. Nodular glomerulosclerosis of the kidney (Kimmelstiel-Wilson disease).

A Building Block approach to treating hypertension

With these three therapeutic building blocks
you can create a once-a-day regimen to fit almost any degree
of hypertension. See the following pages for details . . .

Consider starting your hypertensives on this basic thiazide

A single daily dose of Enduron provides sodium excretion around the clock

Enduron is a true 24-hour single-dose thiazide. Its sodium excretion is not squeezed into an abrupt peak during the first several hours. It is well-sustained in a plateau-like effect—with little reduction for the first 12 hours, and decline thereafter only gradual.

Potassium loss, by contrast, is low. It reaches an early minor peak, then subsides rapidly. Moreover, since dosage is but once a day, there is but one daily peak of potassium loss. As with all thiazides, however, dietary potassium supplementation should also be considered, especially in long or intensive therapy.

Use Enduron as an ideal starting therapy in mild hypertension. Use it too, as a basic therapeutic building block with which other agents can be joined, for managing your more resistant hypertensives.

Once a day, every day

ENDURON[®]
METHYCLOTHIAZIDE

DAILY
DOSAGE
RANGE

Minimum

2.5 mg. tablet

Usual

5 mg. tablet

Intermediate

7.5 mg.

Maximum

10 mg.

See Brief Summary on final page of advertisement.

To build added response, shift to Enduronyl

The deserpidine component adds enhanced antihypertensive activity

The rauwolfia component of Enduronyl is deserpidine (Harmony[®]), a purified crystalline alkaloid supplied only by Abbott. It augments Enduron with its own antihypertensive and tranquilizing action.

Thus the combined clinical effect of these two therapeutic building blocks in Enduronyl is greater than can ordinarily be achieved with either alone.

To add flexibility, Enduronyl comes in two strengths: regular and Forte. Both provide 5 mg. of Enduron. The variation is where most helpful: in the deserpidine. The tablets are scored, and give a surprisingly wide and economical choice of once-a-day doses (see below).

Choose Enduronyl for your patients in the broad range of mild to moderate hypertension. Patient acceptance is excellent!

Once a day, every day

ENDURONYL[®]

METHYLOTHIAZIDE 5 MG. WITH DESERPIDINE 0.25 MG.

ENDURONYL FORTE

METHYLOTHIAZIDE 5 MG. WITH DESERPIDINE 0.5 MG.

	Minimum	Usual	Intermediate	Maximum
DAILY DOSAGE RANGE	 2.5 mg. methyclothiazide 0.125 mg. deserpidine	 5 mg. methyclothiazide 0.25 mg. deserpidine	 7.5 mg. methyclothiazide 0.375 mg. deserpidine	 10 mg. methyclothiazide 0.5 mg. deserpidine
DAILY DOSAGE RANGE	 2.5 mg. methyclothiazide 0.25 mg. deserpidine	 5 mg. methyclothiazide 0.5 mg. deserpidine	 7.5 mg. methyclothiazide 0.75 mg. deserpidine	 10 mg. methyclothiazide 1 mg. deserpidine

See Brief Summary on final page of advertisement.

Eutonyl affords a different kind of basic therapy for moderate to severe cases

Effect tied to reduced peripheral vascular resistance; no central depressant action

Eutonyl is a unique nonhydrazine agent. It is reported to act by reducing peripheral vascular resistance.^{1,2}

In clinical trials, significant reductions in mean blood pressure were seen in 84% of patients studied—all were moderate to severe cases. Eutonyl lowers diastolic in proportion to systolic, and in about half of the cases studied, reductions in the sitting and recumbent positions were nearly as great as in the standing position.

Most important: There is no central depressant action. In fact, some patients reported an *increased* sense of well being.

Here, then, is a highly effective *basic treatment* for moderate to severe cases—and one that will not hamper your patient with lethargy or drowsiness while on treatment.

Once a day, every day

EUTONYL®
PARGYLINE HYDROCHLORIDE

DAILY DOSAGE RANGE	Minimum	Usual starting	Intermediate	Maximum
	 10 mg. tablet	 25 mg. tablet	 50 mg. tablet or as needed	 200 mg.

1. Brest, A. N., et al., Cardiac and Renal Hemodynamic Response to Pargyline, *Ann. N. Y. Acad. Sci.*, 107-1016, 1963.

See Brief Summary on final page of advertisement.

Eutron adds thiazide for enhanced therapy with milder side effects

Only a 7/4 mm. span between standing and recumbent pressures in clinical trials—reduced chance of orthostatic hypotension

The combining of Eutonyl and Enduron in Eutron permits a significantly greater antihypertensive effect than with either agent used alone. This in turn may allow therapeutic success with lesser dosage—and correspondingly milder side effects.

A significant finding in clinical trials was the drug's action in lowering blood pressure to *nearly equal levels in all body positions*. Total average spread between standing and recumbent readings (after treatment) was only 7/4 mm. Hg.

Thus, in your moderate to severe cases, Eutron affords a usually smooth course of therapy, often with reduced likelihood of orthostatic effects. (The usual precautions against rising suddenly, of course, will always apply.) And, because of the thiazide component, Eutron may be used in the presence of congestive heart failure.

Once a day, every day

EUTRON™

PARGYLINE HYDROCHLORIDE 25 MG.
WITH METHYCHLOTHIAZIDE 5 MG.

DAILY DOSAGE RANGE

Minimum

12.5 mg. pargyline hydrochloride and 2.5 mg. methyclothiazide

Usual starting

25 mg. pargyline hydrochloride and 5 mg. methyclothiazide

Intermediate

37.5 mg. pargyline hydrochloride and 7.5 mg. methyclothiazide

Maximum

50 mg. pargyline hydrochloride and 10 mg. methyclothiazide

See Brief Summary on final page of advertisement.

TM—Trademark

707075-R

ENDURON[®] | ENDURONYL[®]

METHYLCLOTHIAZIDE

Each tablet contains
Methyclothiazide 5 mg. with
Deserpidine 0.25 mg. or 0.5 mg.

Indications: Enduron is used to control edema and mild to moderate hypertension; also used with other drugs for hypertension. Enduronyl is used in mild to moderately severe hypertension; when used with Enduronyl, more potent agents can be given at reduced dosage to minimize undesirable side effects.

Contraindications: Neither Enduron nor Enduronyl should be used in severe renal disease (except nephrosis) or shutdown; in severe hepatic disease or impending hepatic coma; in patients sensitive to thiazides. Hepatic coma has been reported as a result of hypokalemia in patients receiving thiazides.

Enduronyl is contraindicated in patients with severe mental depression and suicidal tendencies, active peptic ulcer, or ulcerative colitis.

Warnings: Consider possible sensitivity reactions in patients with a history of allergy or asthma. If added potassium intake is indicated, dietary supplementation is recommended. Enteric-coated potassium tablets should be reserved for cautious use only when adequate dietary supplementation is not practical because those tablets may induce serious or fatal small bowel lesions consisting of stenosis with or without ulceration. These small bowel lesions have caused obstruction, hemorrhage and perforation frequently requiring surgery. Medication should be discontinued immediately if abdominal pain, distension, nausea, vomiting or GI bleeding occurs.

Precautions: Use thiazides with caution in severe renal dysfunction, impaired hepatic function, or progressive liver disease. In surgical patients, thiazides may reduce the response to vasopressors and increase the response to tubocurarine. Use thiazides with caution in pregnancy (bone marrow depression, thrombocytopenia, or altered carbohydrate metabolism have been reported in certain newborn infants). Also reported have been: blood dyscrasias including thrombocytopenia with purpura, agranulocytosis and aplastic anemia; elevations of BUN, serum uric acid, or blood sugar. Symptomatic gout may be induced. Antihypertensive response may be enhanced following sympathectomy.

Use Enduronyl with caution in patients with a history of peptic ulcer, as rauwolfias may increase gastric secretion. Discontinue at the first sign of mental depression. Rauwolfia alkaloids may increase hypotensive effects of surgery or anesthesia, and should be discontinued two weeks prior. They also lower the convulsive threshold and shorten seizure latency. In epilepsy, dosage adjustment of anticonvulsant medication may be necessary. Alcohol, barbiturates, or narcotics may potentiate action of deserpidine.

Adverse Reactions: During intensive or prolonged therapy, guard against hypochloremic alkalosis and hypokalemia (especially the latter if patient is on digitalis). All patients should be observed for signs of hyponatremia ("low-salt" syndrome). Reported thiazide reactions include: anorexia, nausea, vomiting, diarrhea, headache, skin rash, dizziness, paresthesia, weakness, photosensitivity, jaundice, and pancreatitis.

Reported rauwolfia reactions include: nasal stuffiness, nausea, weight gain, diarrhea, aggravation of peptic ulcer, epistaxis, skin eruption, and reduction of libido and potency. Excessive drowsiness, fatigue, weakness, and nightmares may signal early signs of mental depression.

EUTONYL[®] | EUTRON[™]

PARGYLINE HYDROCHLORIDE

Each tablet contains
Pargyline Hydrochloride 25 mg.
with Methyclothiazide 5 mg.

Indications: For treatment of patients with moderate to severe hypertension, especially those with severe diastolic hypertension. Not recommended for patients with mild or labile hypertension amenable to therapy with sedatives and/or thiazide diuretics alone. It is desirable to establish the dosage of Eutron by administering component drugs separately.

Contraindications: Pheochromocytoma, advanced renal disease, increasing renal dysfunction, paranoid schizophrenia and hyperthyroidism. Hepatic coma has been reported as consequence of hypokalemia with thiazide therapy. Until further experience is gained not recommended for patients with malignant hypertension, children under 12, or pregnant patients.

Concomitant use of the following is contraindicated: other monoamine oxidase inhibitors; parenteral forms of reserpine or guanethidine; sympathomimetic drugs; foods high in tyramine such as cheese; imipramine and amitriptyline, or similar antidepressants; methyl dopa. 2 week interval should separate therapy and use of these agents.

Methyclothiazide is contraindicated in patients with known sensitivity to thiazides.

Warnings: Pargyline hydrochloride is a monoamine oxidase inhibitor. Warn patients against eating cheese, and using alcohol, proprietary drugs or other medication without the knowledge of the physician. When indicated, alcohol, narcotics (meperidine should be avoided), antihistamines, barbiturates, chloral hydrate, and other hypnotics, sedatives, tranquilizers, or caffeine, may be used cautiously in reduced dosage. In emergency surgery $\frac{1}{4}$ to $\frac{1}{2}$ the usual dose of narcotics, analgesics, and other premedications should be used avoiding parenteral administration where possible. Carefully adjust dose of anesthetics to response of patient. Withdraw pargyline two weeks before elective surgery.

Warn patients about the possibility of postural hypotension. Those with angina or coronary artery disease should not increase physical activity with an improvement in well being. Pargyline may lower blood sugar.

Avoid use of enteric-coated potassium tablets, as these may induce serious or fatal small-bowel lesions consisting of stenosis with or without ulceration. These small-bowel lesions have caused obstruction, hemorrhage and perforation frequently requiring surgery. Medication should be discontinued immediately if abdominal pain, distension, nausea, vomiting or GI bleeding occurs. These products contain no added potassium salts and if added potassium intake is desired, dietary supplementation is recommended. Coated potassium tablets should be reserved for cautious use when adequate dietary supplementation is impractical. In patients with a history of allergy or asthma the possibility of sensitivity reactions should be considered.

Precautions: Measure blood pressure while patient is standing to determine antihypertensive effect. Use with caution in hyperactive or hyperexcitable persons. Such persons may show increased restlessness and agitation. Withdraw drug during acute febrile illness. Watch patients with impaired renal function for increasing drug effects or elevation of BUN and other evidence of progressive renal failure; withdraw drug if such alterations persist and progress. Use with caution in patients with liver disease. As with all new drugs, complete blood counts, urinalyses, and liver function tests should be performed periodically. With prolonged therapy, examine patients for change in color perception, visual fields and fundi. Also reported have been: blood dyscrasias including thrombocytopenia with purpura, agranulocytosis and aplastic anemia; elevations of BUN, serum uric acid, or blood sugar. Symptomatic gout may be induced. In surgical patients thiazides may reduce response to vasopressors and increase response to tubocurarine.

Adverse Reactions: Pargyline may be associated with orthostatic hypotension. Mild constipation, slight edema, dry mouth, sweating, increased appetite, arthralgia, nausea and vomiting, headache, insomnia, difficulty in micturition, nightmares, impotence, delayed ejaculation, rash, and purpura have been encountered with pargyline. Hyperexcitability, increased neuromuscular activity (muscle twitching) and other extrapyramidal symptoms have been reported in a few patients with reduced cardiac reserve.

During intensive or prolonged therapy, guard against hypochloremic alkalosis and hypokalemia (especially the latter if patient is on digitalis). Observe all patients for signs of hyponatremia ("low salt" syndrome).

Reported thiazide reactions also include anorexia, nausea, vomiting, diarrhea, headache, dizziness, paresthesia, weakness, skin rash, photosensitivity, jaundice, and pancreatitis. Nocturia has been observed with the combination.

709075R

Untoward Reactions Associated with Antimicrobial Therapy

Part III. Metabolic and Electrolytic, Skeletal, Neuromuscular, and Dermal Reactions with
Comment and Conclusions*

Metabolic and Electrolytic

Antianabolic Effect

The tetracyclines can produce an antianabolic effect that is manifested by negative nitrogen balance, increased azotemia, hyperphosphatemia, and urinary loss of sodium, but the effect is rarely significant in patients with normal renal function.

Sodium Potassium

As briefly mentioned in Part I, some antibiotics should be used with caution in patients with cardiac or renal diseases because of the increased intake of sodium or potassium intrinsic in therapy with these drugs. For example, cephalothin has a sodium content of 55 mg/Gm. whereas each 4 Gm. of methicillin supplies 230 mg. of sodium, and each 15,000,000 units of potassium penicillin G contains 975 mg. of potassium.

Hypocholesterolemic Effect

Neomycin-induced malabsorption is a possible explanation of the hypocholesterolemic effect that follows oral administration of the drug. In a study by members of our group, patients were given neomycin for one week in a daily dose of 4 Gm. and the average decrease in the value for plasma cholesterol was 15%.¹

Glycosuria

Administration of bacitracin may result in glycosuria. Use of nalidixic acid may result in false-positive reactions for urinary glucose, and possibly true glycosuria. Cephalothin also has

caused false-positive reactions for glycosuria. The sulfonamides may have a hypoglycemic effect.

Nalidixic acid may have an antipyretic action similar to that of aspirin.

Among the multiple untoward effects of therapy with amphotericin B is hypokalemia, and determination of the concentration of serum potassium should be made periodically.

The sulfonamides may precipitate an exacerbation of porphyria hepatica in susceptible persons.

Skeletal

Despite the terminology, the syndrome of serum sickness is now caused more frequently by drugs than by serum products. Myalgia and arthralgia are frequent, but true synovitis is rare. The syndrome is usually noted within several days of receipt of the antimicrobial drug, and a penicillin appears to be most commonly responsible. In addition to the skeletal manifestations, a rash, lymphadenopathy, varied degrees of edema, fever, and other findings may occur. The reaction may subside in 48 hours, or it may persist for two weeks or more.

The tetracyclines are retained in bone, apparently because of the chelating properties of these agents and formation of a stable, insoluble tetracycline-calcium-orthophosphate complex. Ultra-violet fluorescent microscopy has revealed deposits of a tetracycline that are bright yellow in newly deposited bone, calcified cartilage, and extra-skeletal calcification. If a tetracycline is administered at a specific time before bone sampling, the amount of cortical bone formed between labeling and sampling can be measured.

*See Parts I and II, Minnesota Med. 50:1393 and 50:1571, 1967.

In rats, administration of a tetracycline during the tenth to the fifteenth day of gestation results in a considerable reduction in expected fetal size at term. As aforementioned, the question has been raised whether deposition of the drugs in bone might inhibit linear bone growth in infants, especially in those born prematurely. Fluorometry has revealed transplacental deposits of the tetracyclines throughout the human fetal skeleton. In such cases there is reversible depression of skeletal growth on short-term administration of the tetracycline.

Bulging fontanelles have occurred after administration of a tetracycline in infants, but this has disappeared on cessation of treatment.

Neuromuscular

In considering the possible neurotoxic reactions, one is impressed with the number of antimicrobial drugs that may involve the eighth cranial nerve in an untoward manner.

Vestibular Effect

Vestibular involvement may be characterized initially by some vertigo, but this is frequently difficult to verify because the patient is in bed most of the time. Also, in the initial stage, the dysequilibrium may be difficult to substantiate by physical examination, the nystagmus may be inconstant, and only vestibular-turning tests may be capable of detecting early signs of otic damage. The vestibular damage may be confirmed clinically during the subsequent two or three months, but later on the dysequilibrium usually decreases to a considerable degree, mainly because of compensatory visual mechanisms. However, the degree of compensation may not be optimal in patients of advanced age.

Cochlear Involvement

Cochlear involvement is more serious, because compensated dysequilibrium is preferable to deafness, and almost always the hearing loss is irreversible even if the treatment is stopped. Characterized at first by a decrease in hearing high frequencies, detectable only by the audiogram, the deafness proceeds progressively to conversation frequencies and hypoacusia, if treatment is continued. The obvious disproportion of the residual functional deficit between cochlear and vestibular damage accounts for the current recommendation

that one use streptomycin, which is more likely to induce vestibular toxicity, in preference to dihydrostreptomycin, which is more likely to damage the cochlear portion of the eighth nerve. Other antimicrobial drugs capable of causing cochlear damage are kanamycin, neomycin, and vancomycin. Whether ristocetin or colistin is ototoxic is uncertain. One should avoid concurrent and, perhaps, sequential use of these ototoxic drugs. The likelihood of ototoxicity is greater in infants, the aged, dehydrated patients, and those with impaired renal function. Individual susceptibility to the causative drugs may also have a role in the genesis of damage to the eighth nerve; and although the daily dose and duration of the treatment are important factors, it is almost impossible to establish absolute security against ototoxicity in all cases. Although the ototoxicity of these drugs when given intramuscularly or intravenously is well recognized, it is less well appreciated that otic damage after use of some of them has occurred from their intrapleural instillation, topical application to cutaneous burns, aerosolization, and oral administration. To avoid ototoxicity after oral administration of kanamycin or neomycin, the total daily dosage should not exceed 4 Gm.^{2,3}

Detection of early vestibular and cochlear complications can best be achieved if audiograms and vestibular-turning tests are done before, during, and at the conclusion of treatment. Also, monitoring of the serum levels of these drugs, especially in predisposed subjects, is advisable. The blood concentration of streptomycin should not exceed 25 µg/ml. and the daily dose should be adjusted accordingly. With normal renal function and in keeping with the total body weight of the recipient, ototoxic effects are generally unlikely if no more than 2 Gm. of streptomycin are given daily for no longer than 14 days, or 1 Gm. is administered daily for as long as four weeks. In order to minimize ototoxicity due to neomycin or kanamycin, blood levels should not exceed 15 µg/ml.; for an adult of average weight the daily parenteral dose is 1 Gm., and one should be hesitant to continue treatment beyond 14 days.

Optic Neuritis

Optic neuritis, with consequent impairment of vision, is observed occasionally on use of isoniazid, chloromycetin, and streptomycin;⁴ the mechanism of this complication may be related to drug-

induced pyridoxine deficiency. Use of a tetracycline may be followed by acute transitory myopia.⁵ Administration of amphotericin B has caused diplopia, and polymyxin B, colistin, and nalidixic acid have induced visual disturbances.

Cortical Irritation

Penicillin G, when given in large amounts, may cause cortical irritation, including convulsions, especially in patients with decreased renal function. Chronic brain damage may result. Since anaphylactic reactions to penicillin G may also be characterized by convulsions and result in chronic brain damage, one should perhaps be more aware of the potential neurotoxicity of the drug. Convulsions also may follow use of cycloserine (Seromycin) and amphotericin B.

Other untoward effects of cycloserine, involving the nervous system, include headache, tremor, dysarthria, paresis, and dyskinesia and generally appear within the first week or two of treatment. There are some data indicating that untoward effects of this drug are prevented or controlled by concomitant administration of pyridoxine, either alone or in combination with anticonvulsants, tranquilizers, and sedatives. The antibiotic should be used with caution in patients who have impaired renal function and is contraindicated in patients with a history of epilepsy. One should be hesitant to prescribe nalidixic acid for patients with a history of epilepsy, since stimulation of the central nervous system has occurred after the drug has been used.

Polymyxin B and colistin have caused vertigo, cerebellar ataxia, and transitory disturbances in speech, among other untoward reactions involving the central nervous system.

Intrathecal injection of antimicrobial drugs, especially when they are administered in amounts exceeding the recommended dose, may result in arachnoiditis; causative drugs have included penicillin G, streptomycin, and polymyxin B.

Psychic Nature

Untoward reactions of a psychic nature may be associated with use of different antimicrobial drugs, but usually the reactions are not specific; headache, insomnia, weakness, drowsiness, and the like may occur. However, some of these drugs can cause acute psychoses with agitation, confusion, delirium, and hallucinations among other manifestations; penicillin G, the sulfapyrimidines,

and cycloserine are potentially causative; but generally, the reaction disappears when use of the offending drug is discontinued.

Psychomotor incoordination may follow administration of certain antimicrobial drugs, such as polymyxin B, colistin, the sulfapyrimidines, and griseofulvin. In some patients the reaction is sufficiently severe to warrant the advice that they not drive vehicles or use hazardous machinery.

Peripheral Neuropathy

Peripheral neuropathy may occur during treatment with streptomycin, dihydrostreptomycin, neomycin, kanamycin, chloramphenicol, polymyxin B, colistin, nitrofurantoin, the sulfonamides, amphotericin B, and griseofulvin. Some of these drugs may induce this reaction by depletion of pyridoxine. All four extremities may be involved, and clinically one may see motor changes associated with sensory abnormalities. Absence of reflexes, gradual onset of paralysis, and serious complications such as pseudotabetic syndromes are seen mainly when treatment is not discontinued.

Streptomycin, dihydrostreptomycin, neomycin, kanamycin, polymyxin B, and colistin are commonly responsible for paresthesias, usually circumoral and of the acral parts. As an isolated finding, paresthesias are not an indication for discontinuing treatment with these drugs. Paresthesias occurring during treatment with other drugs, such as nitrofurantoin or griseofulvin, probably warrant discontinuation of therapy, for fear of inducing peripheral neuropathy.

Curariform Action

As noted previously, streptomycin, dihydrostreptomycin, neomycin, kanamycin, polymyxin B, and colistin are capable of a potential curariform action. This may result in neuromuscular block and consequent respiratory or cardiac arrest. Such an effect is most likely to occur on intraperitoneal or intrapleural administration of these antibiotics and would be most unusual when the drugs are given intramuscularly. Nevertheless, the possibility should be considered in infants, in the aged, in patients with renal disease or hypoxic states, and in those receiving certain drugs such as muscle relaxants, sedatives, narcotics, and anesthetic agents. Of course, use of these antibiotics is contraindicated in patients who may have my-

asthenia gravis. Neostigmine, 0.25 mg. given intravenously, with the dose increased as necessary, may control the neuromuscular block. Edrophonium given intravenously in amounts of 10 mg. has also been recommended. In cases of neuromuscular block due to polymyxin B or colistin, intravenous use of calcium may be more effective than neostigmine or edrophonium.

Also, as aforementioned, increased intracranial pressure with bulging fontanelles has been observed after administration of a tetracycline to infants, but the pressure has disappeared on cessation of treatment.

The Gray Syndrome

The "gray syndrome," after administration of chloramphenicol to infants has also been described previously. Among the manifestations of this complication, lethargy, flaccidity, and respiratory distress may occur.

The most common cause of *Pseudomonas* meningitis is said to be a diagnostic spinal tap. As noted earlier, these "water bacilli" are frequently present in various fluids and on medical instruments exposed to fluids. If instruments used in aspiration of the spinal fluid are exposed to solutions contaminated with *Pseudomonas* organisms, iatrogenic infection may occur. Infection with these bacilli is abetted if the patient is receiving an agent, such as a penicillin, erythromycin, or lincomycin, to which these organisms are resistant.

After intramuscular injection of certain antimicrobial agents, pain, induration, and inflammation may occur at the site. Sterile abscesses rarely eventuate. Of the penicillins, benzathine, penicillin G, ampicillin, and nafcillin appear to be most likely to produce pain on intramuscular injection. Intramuscular administration of tetracycline is more likely to produce pain than is oxytetracycline or rolitetracycline. Other antimicrobial drugs that are commonly painful on intramuscular injection are erythromycin, bacitracin, and polymyxin B. In some patients, especially when the dose of 0.5 Gm. is exceeded, pain on intramuscular injection of cephalothin may require addition of a local anesthetic agent to the solution.

Arthus Phenomenon

The Arthus phenomenon may progress to an extensive hemorrhagic necrosis and ulceration, extending into the muscle. However, since the reaction is rare, at least in its more pronounced

manifestations, one should be reticent in concluding that a given lesion exemplifies the phenomenon. Lesions simulating the reaction and occurring more commonly may be due to intrinsically irritating properties of the injected drug or to secondary infection at the injection site.

As aforementioned, the sulfonamides are capable of precipitating exacerbations of porphyria in susceptible persons, and involvement of the nervous system in such patients is not infrequent. Also, the sulfonamides and numerous other drugs may be responsible for aggravation of disseminated lupus erythematosus, and various neural deficits may be among the clinical findings.

So-called drug fever may occur on administration of any antimicrobial drug. It has been postulated that this reaction might be of central origin, but there appears to be no precise evidence of a direct effect on the thermal centers. The reaction usually is believed to be a hypersensitivity one; conceivably, products released by injured cells of the "shock organs" involved might indirectly affect the thermal centers.

Dermal

Dermal reactions, including angioneurotic edema and contact dermatitis, may occur after the use of any antimicrobial drug, but among those commonly used, streptomycin, the tetracyclines, and erythromycin are least likely to be causative; conversely, the penicillins, novobiocin, and the sulfonamides are most likely to be causative. Within several days of receipt of an antimicrobial agent there may occur pruritus followed by a rash which may be erythematous, morbilliform, petechial, or purpuric, but is most commonly urticarial. Purpuric lesions may be more frequent after administration of the penicillins, novobiocin, and the sulfonamides. Most dermal reactions subside within a few days after discontinuation of therapy with the offending antimicrobial drug, but rarely the process eventuates in a more serious condition, such as exfoliative dermatitis.

Novobiocin is clinically about as effective as erythromycin against susceptible organisms, but the chief objection to its use is the occurrence of allergic dermatitis in 5 to 10% of patients receiving the drug.

Arthus Phenomenon

The Arthus phenomenon may progress from a

red erythematous area at the site of injection of an antimicrobial drug to an extensive hemorrhagic necrosis and eventual ulceration of subcutaneous tissue and even muscle.

The Stevens-Johnson syndrome (erythema multiforme exudativum) has been noted after the use of certain antimicrobial drugs that include the sulfonamides and novobiocin.

Administration of nitrofurantoin is rarely followed by transient alopecia.

Fluorescence and Photosensitivity

In patients having received prolonged therapy with the tetracyclines, fluorescence of the proximal part of the nails may be demonstrable. Sometimes significant discoloration and onycholysis can be seen with the naked eye.⁶

Photosensitivity, manifested by marked erythema with or without edema, while more frequently associated with the use of demethylchlor-tetracycline, was reported early in the experience with chlortetracycline and more recently on administration of tetracycline and oxytetracycline. Griseofulvin, nalidixic acid, and certain sulfonamides may also be photosensitizing.

As mentioned earlier, *Pseudomonas* organisms exemplify the so-called water bacilli which may contaminate various fluids. *Pseudomonas* bacteremia may follow local application of contaminated medications applied to various dermal diseases and injuries, such as eczematoid dermatitis and extensive burns.

Disseminated lupus erythematosus may be precipitated by several antimicrobial drugs, but probably a penicillin or a sulfonamide has been most commonly responsible. Porphyria, especially in the form of cutanea tarda, may also be precipitated by use of a sulfonamide.

Comment

In the light of our present knowledge, the mechanism involved in the genesis of many untoward reactions to antimicrobial drugs is believed to depend on antigen-antibody combinations, which may attack certain cells selectively for reasons that are not entirely clear. Unlike foreign proteins, antimicrobial drugs are not complete antigens and probably combine in the host's body with protein in a hapten-like manner in order to become antigenically effective. Development of hypersensitivity reflects contact with the allergen

and the individual's capacity for sensitization, which is constitutionally or genetically determined.

Allergic Reactions

Among antimicrobial drugs, the penicillins are the leading cause of allergic reactions. Cross-allergenicity among the semisynthetic and natural penicillins apparently is reflective of the fact that they share the 6-APA nucleus. It is theorized that a catabolic product, or products, of the penicillins (penicilloyl compounds as an example) may unite with body protein and cause most of the allergic reactions. The anticipation of an allergic reaction, a history of adverse reactions to a penicillin in the past, or the report that the patient previously exhibited other manifestations of allergy, particularly asthma, remain important despite the increasing validity of various tests. There are three drugs of adjunctive use that can cause allergic reactions and hence confusion with those produced by penicillin G; these are procaine, probenecid (Benemid), and penicillinase.

Cross-Resistance

Partial or one-way bacterial cross-resistance among streptomycin, neomycin, kanamycin, and paromomycin is usual; streptomycin-resistant strains may be susceptible to the other drugs, but organisms insensitive to neomycin, kanamycin, or paromomycin usually resist streptomycin as well. Generally there is complete cross-resistance among organisms able to resist neomycin, kanamycin, and paromomycin. It is thus apparent that indiscriminate use of any of these drugs is to be avoided in order to minimize the development of bacterial resistance to them. It is to be noted that bacterial resistance to neomycin has increased in recent years, apparently because the drug has been incorporated in procedures used to prepare the colon preoperatively, and because neomycin is a constituent of various preparations for local use, such as creams and ointments.

The incidence of nausea and vomiting after oral use of the tetracyclines is reduced if the agent is given with cold pasteurized milk, which may be undesirable, however, in patients receiving a low-residue or low-sodium maintenance diet. Milk may depress the concentration of drug in the blood and cannot be tolerated by some individuals. In such circumstances, calcium carbonate in amounts of 5 grains with each capsule of the antibiotic is substituted. Although calcium carbonate,

like calcium-containing foods and other antacids, may hinder the absorption of the tetracycline, blood levels usually are higher than when one resorts to the alternative of reducing the dose of the antibiotic.

Because the tetracyclines are retained in mineralized tissues, including neoplastic bone, these drugs may have potential use in determining the level of amputation in osseous tumors. The affinity of the tetracyclines for tumor cells is also being investigated, and tetracycline-fluorescence of malignant tissue may complement conventional procedures in the study of tumors of the urinary bladder, and in search of neoplastic cells in sputum and in gastric, duodenal, pleural, and ascitic fluids. Also, a tetracycline tends to accumulate in damaged but still viable tissue; consequently, the radioactivity of a tagged tetracycline may help indicate ischemic areas, such as those in the myocardium and kidney, and might help define the extent of burns.

Because of the possibility that L-phenylalanine may ameliorate chloramphenicol-induced hematotoxicity, there has evolved the hypothesis that, in some cases at least, the untoward effects of chloramphenicol on the bone marrow may be due to diminished absorption of phenylalanine from the intestinal tract rather than to a direct cellular effect of the drug. However, as aforementioned, some workers disagree with the conclusion that L-phenylalanine has a salutary effect in cases of chloramphenicol-induced hematotoxicity.

Erythromycin base is almost unique among antimicrobial drugs because of the paucity of untoward reactions associated with its use.⁷ Mild gastrointestinal irritation may follow oral use of the agent, but there is little evidence of serious allergic reactions to erythromycin base. Among the kindred drugs, hepatic dysfunction, which may follow use of erythromycin estolate and triacetyloleandomycin, limits the wider use of these agents. The relatively high incidence of allergic dermatitis militates against more common use of novobiocin. There has been insufficient study of lincomycin to allow precise assessment of its toxicity, but d'arrhea has required discontinuation of its use in 2 to 3% of patients, and hepatotoxicity, neutropenia, and superinfection are possible complications of its use.

If the production of less pain on intramuscular injection is taken as a paramount advantage of colistin over polymyxin B, one should recall that

employing a 1 to 2% solution of procaine (Novocain), lidocaine (Xylocaine), or a similar preparation in making dilutions of polymyxin B will provide the same effect. Except for the consideration of pain at the injection site, the untoward reactions after use of these two drugs are virtually identical in type and degree, although it has been suggested that colistin may have additional forms of toxicity.⁸

Among the less commonly employed antimicrobial drugs are the nephrotoxic bacitracin, the ototoxic vancomycin, the hematotoxic ristocetin, and the neurotoxic cycloserine. Today these drugs are less commonly used for their systemic effect, because effective drugs that are less toxic have become available. However, in patients allergic to the penicillins, who have serious staphylococcal infections, such as endocarditis, some workers prefer vancomycin to cephalothin.

A difficulty with the use of cephalothin stems from an apparent dichotomy between in-vitro bacterial susceptibility and in-vivo achievability, especially in infections due to certain strains of staphylococci, *Neisseria*, *Salmonella*, *Shigella*, and *Haemophilus influenzae*.

It appears to remain the consensus among physicians with a special interest in infectious diseases that a significant degree of cross-allergenicity between cephalothin and the penicillins is unlikely, but the possibility is not entirely excluded. Some patients allergic to the penicillins have had untoward reactions to cephalothin, but a goodly number have not; in this regard, it should be recalled that patients allergic to the penicillins have taken the drugs at a later date without untoward incident.

Cephalothin, while evidently resistant to staphylococcal penicillinase, may be degraded by a similar enzyme, cephalosporinase, which is also of bacterial origin. Cephalosporinase, like penicillinase, appears to be a beta-lactamase which acts on the beta-lactam ring of cephalothin. It is not agreed at present whether organisms produce different beta-lactamases, some with primarily cephalosporinase activity, or produce only one enzyme which has varying cephalosporinase-penicillinase ratios. In any event, if such enzymes cause future clinical problems, such as contributing to bacterial resistance, there is the possibility of synthesizing cephalosporinase-resistant cephalosporins.

The sulfonamides currently available are undoubtedly less toxic than those employed previously, but it is well to remember that any of them can conceivably be responsible for such untoward reactions as nephrotoxicity, blood dyscrasias, the Stevens-Johnson syndrome, and periarteritis nodosa. Anaphylaxis, hepatitis, pancreatitis, cyanosis, purpura, conjunctivitis, and "serum sickness" are uncommon with the compounds in current use. Cross-hypersensitivity to various sulfonamides, as well as to chemically related drugs (for example, tolbutamide), is common. The decreased detoxification of the sulfonamides in patients with hepatic dysfunction should be borne in mind.

Use of methenamine mandelate (Mandelamine) may cause gastrointestinal irritations and skin rashes; the drug is contraindicated in renal insufficiency. It is recommended that methenamine mandelate not be given conjointly with the sulfonamides, because sulfamethizole and sulfathiazole may form an insoluble precipitate with formaldehyde in the urine.

Among the nitrofurans, nitrofurantoin and furazolidone (Furoxone) may produce a disulfiram-type reaction; consequently patients receiving these drugs should be advised to refrain from ingestion of alcoholic drinks. So-called nitrofuran neuropathy⁹ is usually reversible but not invariably so.

Nalidixic acid is capable of potential untoward reactions involving several systems of the body. Among these reactions are visual disturbances, stimulation of the central nervous system, possible hepatotoxicity, increased azotemia, and photosensitization. Because of these reactions and because the drug's antibacterial spectrum is virtually limited to *Escherichia coli*, the long-term application of the drug is somewhat questionable. Strains of *E. coli*, resistant to nalidixic acid, have emerged during therapy, and bacterial resistance to nalidixic acid appears to increase in a given environment in direct proportion to the amount of the drug employed therein.

Amphotericin B must be numbered among the drugs with the highest potential for untoward reactions, and these run the entire gamut of the bodily systems.¹⁰ The drug continues to be employed because it is effective, and there is no alternate drug in most diseases of mycotic or fungal origin.

Nystatin, which is not absorbed from the gastrointestinal tract but is sometimes given orally in

an attempt to combat candidal enterocolitis, may cause nausea, vomiting, and diarrhea but rarely causes untoward reactions of a systemic nature.

Griseofulvin, which is absorbed from the gastrointestinal tract, represents a distinct step forward in the management of susceptible fungal infections. However, it may cause untoward reactions involving several systems of the body; these effects include peripheral neuropathy, photosensitization, and gynecomastia. Because griseofulvin is derived from species of *Penicillium*, the possibility of a cross-sensitivity reaction exists.

Because of the ever-increasing ability of man to synthesize (or semisynthesize) effective antimicrobial drugs, an apparent advantage provided by a chemical change in a drug may be accompanied by disadvantages that are not characteristic of the parent compound and which therefore may not be immediately evident. The unexpected hepatotoxicity due to the propionyl ester of erythromycin and that due to triacetyloleandomycin are examples of undesirable effects, not characteristic of the parent drugs, which may accompany a chemical change in an antimicrobial drug that initially appeared to represent a more desirable product. Other examples of this phenomenon include the increased photosensitizing capacity of demethylchlortetracycline and the greater incidence of nephrotoxic and hematotoxic reactions associated with the use of methicillin, when compared with use of the parent drugs.

Conclusions

All antimicrobial drugs are capable of provoking untoward reactions, and almost any organ in the body may be involved. However, the ability of individual antimicrobial drugs to result in untoward reactions is variable and ranges from the minimal capacity of erythromycin to that of amphotericin B, which is capable of causing multiple ill effects and of affecting virtually every system of the body. Fortunately, the antimicrobial drugs that are most commonly employed are intermediate in their capacity to provoke untoward reactions. As a consequence of the increasing number of new antimicrobial drugs or chemical modifications of older ones, continuous reevaluation of the totality of these drugs is essential, because the benefits, as well as the untoward reactions, may not become evident for months or years after their clinical introduction. Unfortu-

nately, the tendency of patients to exhibit an untoward reaction to an antimicrobial drug cannot be precisely predicted prior to its administration. Previous exposure to an antimicrobial drug is often responsible for an untoward reaction to its use, but some patients experience such a reaction on their first exposure to a therapeutic dose of the drug. Many untoward reactions could be avoided, however, if antimicrobial drugs were used only when indicated and if adequate consideration were given to known preventive aspects. Among the

measures that may minimize the untoward reactions to these drugs are: (1) questioning of the patient to elicit a history of previous untoward reactions to a drug or associated allergies, (2) familiarity with the proper dose of a drug for the patient at hand, (3) awareness of the untoward reactions associated with use of a given drug and their early detection, and (4) employment of a drug only for conditions in which it has known therapeutic value.

Carotid-Pressure Anesthesia

Greek physicians knew the ancient art of producing unconsciousness by pressing on the carotid arteries in the neck. As a matter of fact, the very name carotid comes from the Greek word *karoun* which means heavy sleep.

Even Aristotle wrote in his *History Of Animals*: "If these veins are pressed externally, men, though not actually choked, become insensible and shut their eyes and fall flat on the ground."

Pressure anesthesia, known from prehistoric times, was revived again when Ambroise Pare used this method as early as 1543.

About a year later, it was used by Realdo Colombo in Pisa. As described by the Spanish physician, Valverde, who was present, this was a strange performance. "The carotids," he wrote, "that is, the sleep-producing arteries, are so named because when they are pressed upon or closed up in any way we soon go to sleep. This experiment I saw performed by Realdo Colombo in 1544 in Pisa, on a young man in the presence of a number of gentlemen, with no less fear on their part than amusement on ours, for we gave them to understand that it was done by sorcery."*

QUINAMMTM

Consistently effective, QUINAMM provided complete relief in 94% of 200 patients studied, many of whom were severe cases refractory to other medication.³ Your prescription for one tablet at bedtime often controls painful night cramps with the initial dose . . . helps restore restful sleep.

THE NATIONAL DRUG COMPANY
DIVISION OF RICHARDSON MERRELL INC
PHILADELPHIA, PENNSYLVANIA 19144

Prescribing Information: **Composition:** Each white, beveled, compressed tablet contains: Quinine Sulfate 260 mg. and Aminophylline 195 mg. **Contraindication:** QUINAMM is contraindicated in pregnancy because of its quinine content. **Precautions:** Aminophylline may produce intestinal cramps in some instances, and quinine may produce symptoms of cinchism, such as tinnitus, dizziness, and gastrointestinal disturbance. Discontinue use if ringing in the ears, deafness, skin rash, or visual disturbances occur. **Dosage:** One tablet upon retiring. Where necessary, dosage may be increased to one tablet following the evening meal and one tablet upon retiring. **Supplied:** Bottles of 100 and 500 tablets. **References:** 1. Shumon, C.: Am. J. at the site of infection
(where it counts)...

Ilosone® provides more antibacterial activity than any other oral erythromycin

Acid stable, better absorbed... Ilosone produces faster, higher, more prolonged blood levels, even in the presence of food^{1,3}

Because it is the most active form of oral erythromycin, Ilosone can help assure consistently greater antibacterial activity at the site of infection. Ilosone produces peak antibacterial blood levels two to four times those of other erythromycin preparations.^{1,2} Not only are these levels attained earlier, but they are maintained for much longer periods. Even the presence of food does not seem to affect the activity of Ilosone.^{1,3}

In the treatment of patients with bacterial infections susceptible to erythromycin, Ilosone has compiled an excellent therapeutic record. Since it exerts its greatest activity against gram-positive organisms, it is particularly useful in common respiratory and soft-tissue bacterial infections. Ilosone kills—not merely inhibits—streptococci, pneumococci, and more strains of staphylococci than any other macrolide antibiotic. This bactericidal action, coupled with the high antibacterial levels

attained, makes Ilosone especially valuable in patients with low host resistance, such as infants, debilitated individuals, and diabetics.

Ilosone has shown no cross-resistance with penicillin and may be effective against organisms that have become resistant to that agent. Despite its high antibacterial activity, Ilosone has demonstrated a low incidence of side reactions. Blood dyscrasias, ototoxicity, and tooth staining have not been observed. Infrequent cases of drug idiosyncrasy, manifested by a cholestatic jaundice, have occurred, but there have been no known definite residual effects.

Now available:

New! Ready-mixed Ilosone Liquid 125!
(Contains erythromycin estolate equivalent to 125 mg. erythromycin base per 5-cc. teaspoonful.)

Ilosone®
Erythromycin Estolate

701464

Lilly

(See next page for prescribing information.)

Ilosone®/the most active oral form of erythromycin

Description: Ilosone is the most active form of oral erythromycin that has been developed. Because it is stable in acid, well absorbed, and excreted in lesser amounts in the bile, it provides faster, higher, and longer-lasting levels of antibacterial activity (ABA) in the serum, even when taken with food, than do comparable doses of erythromycin.

Indications: Ilosone is indicated in infections caused by micro-organisms sensitive to its action—especially staphylococci, hemolytic streptococci, and pneumococci.

It has been effective in streptococcus infections, particularly acute bacterial pharyngitis and tonsillitis; staphylococcus disease, including soft-tissue infections, furunculosis, abscesses, cellulitis, carbuncles, and wound infections; pneumococcus pneumonia and acute bronchitis with pneumococci on culture, bronchopneumonia, and otitis media.

In serious staphylococcus infections, erythromycin preparations should be used only in combination therapy with other antimicrobial agents; surgical procedures should be performed when indicated, and large doses of the antimicrobial agents should be employed.

Penicillin is the drug of choice for syphilis and gonorrhea, but Ilosone in multiple 500-mg. doses has been useful in patients with a history of penicillin allergy. Also, other infections due to susceptible bacteria in patients hypersensitive to penicillin or other antibiotics may be considered for treatment with Ilosone.

Contraindications: Known history of sensitivity to this drug; preexisting liver disease or dysfunction.

Adverse Reactions: Hepatic dysfunction with or without clinical jaundice has been reported infrequently. Changes in liver function tests indicative of intrahepatic cholestasis appear to be the result of individual idiosyncrasy. Findings subsided when treatment was discontinued. Occasionally, symptoms simulated extrahepatic obstructive jaundice or the colic of biliary tract disease.

When jaundice appeared to be related to use of the drug, laboratory findings were characterized by increased direct-reacting bilirubin, elevated alkaline phosphatase levels, negative or weakly positive cephalin flocculation and thymol turbidity tests, elevated serum glutamic oxala-

cetic transaminase levels, peripheral eosinophilia, and normal cholecystograms.

Gastro-intestinal disturbances not associated with hepatic effects and occasional allergic manifestations (urticaria, skin eruptions, and, rarely, anaphylaxis) have been reported. The normal intestinal gram-negative bacterial flora is not appreciably altered by erythromycin drugs.

Administration and Dosage: Ilosone is administered orally.

Infants and children under twenty-five pounds, 5 mg. per pound every six hours; twenty-five to fifty pounds, 125 mg. every six hours. Adults and children over fifty pounds, 250 mg. every six hours.

For severe infections, double the dosage. When larger doses are indicated, consider parenteral erythromycin therapy. In beta-hemolytic streptococcus infections, maintain treatment for ten days to prevent rheumatic fever or glomerulonephritis.

In syphilis, a total of 20 to 30 Gm. is administered in divided doses for ten to fifteen days. Close follow-up is necessary since erythromycin drugs have not had adequate evaluation in all stages of syphilis. Examination of spinal fluid is recommended during follow-up.

In gonorrhea, the dosage is 500 mg. four times a day for four days. Patients with a suspected lesion of syphilis should have a dark-field examination before receiving antibiotics and monthly serologic tests for three months. For detailed information, consult the package literature.

How Supplied: Pulvules® Ilosone, Capsules, N.F., 125 mg.* and 250 mg.*

Ilosone Liquid 125, Oral Suspension, U.S.P., 125 mg.* per 5-cc. teaspoonful.

Ilosone, 125, for Oral Suspension, N.F., 125 mg.* per 5-cc. teaspoonful.

Ilosone Drops, 5 mg.* per drop.

Grand Rounds

Hashimoto's Thyroiditis*

ROBERT NOTSKE, M.D.

Medical Resident

IN 1912 HASHIMOTO described four patients with a chronic disorder of the thyroid which he termed struma lymphomatosa. The thyroid glands of these patients were characterized by diffuse lymphocytic infiltration, fibrosis, parenchymal atrophy, and an eosinophilic change in some of the acinar cells.¹ Frequent clinical and pathological studies of this disease have appeared since Hashimoto's original description. The disease has variously been called "Hashimoto's disease," "chronic thyroiditis," "lymphocytic thyroiditis," "lymphadenoid goiter," and recently "auto-immune thyroiditis."

Incidence

Typically, the disease occurs as a painless diffuse enlargement of the thyroid gland in a young or middle-aged woman, often associated with hypothyroidism. Whether the pathologic lesion is the result of one causative agent or many is still unknown. The disease was thought to be uncommon for many years, and the diagnosis was usually made after thyroidectomy or at autopsy. The increasing use of thyroid needle biopsy has led to its more frequent recognition, and some investigators believe it may be increasing in frequency.² The true incidence in the general population is not known, but it is certain that it exists with a much higher frequency than is diagnosed clinically.

The disease is fifteen to twenty times as common in females as in males and occurs especially during the decades from 30 to 60 but may be seen in any age group, including children. DeGroot et al. have reported a number of relatives of patients with Hashimoto's thyroiditis, with moderate enlargement of the thyroid gland and positive antibody studies, but who are entirely

*Presented as a Medical Grand Rounds at Hennepin County General Hospital, January 17, 1967.

asymptomatic. This suggests the possibility of a much higher incidence than is reported.

Pathology

Grossly the tissue involved by Hashimoto's disease is a pinkish-tan to frankly yellowish, and tends to have a rubbery firmness. The goiter is generally quite symmetrical, often with a conspicuous pyramidal lobe. The capsular surface is gently lobulated and non-adherent to perithyroid structures.

Microscopically, one typically sees a diffuse process consisting of a combination of parenchymal atrophy and lymphoid cellular infiltration. The thyroid cells tend to be slightly larger and assume an oxyphilic staining character; they are then called Askanazy cells. The follicular spaces are shrunken, and the colloid is absent or sparse. Within the follicles may be seen clusters of macrophage-like cells. The lymphoid infiltration in the interstitial tissue is accompanied by follicles and germinal centers. Plasma cells are occasionally prominent. Fibrosis may be completely absent or present in degrees ranging from slight to moderate, but rarely severe, as observed in subacute thyroiditis or Riedel's thyroiditis. Foreign body giant cells and granulomas are not features of Hashimoto's disease, in contrast to subacute thyroiditis.

The quantity of parenchymal tissue left in the thyroid is variable. In some instances it is increased, perhaps in a hyperplastic compensatory response to inefficient iodide metabolism.

In addition to the typical disease in which the pathologic process involves the entire lobe or gland, focal thyroiditis which is microscopically similar may be found in the thyroid with diffuse hyperplasia of Graves' disease, in association with thyroid tumors, or in multinodular thyroid glands.¹

Physical Findings

A diffuse, firm goiter with pyramidal lobe enlargement and without signs of thyrotoxicosis should suggest the diagnosis. The association of goiter with hypothyroidism is almost diagnostic of this condition, but it is seen in certain other thyroid conditions. Pain and tenderness are unusual but may be present. A rapid onset is unusual, but the goiter may grow from normal to several times normal size in the period of a few weeks. Most commonly the gland is two to four times normal size. Satellite lymph nodes may be present, especially the "Delphian" node above the isthmus.¹

Laboratory Findings

Laboratory studies may at times be as confusing as helpful. The basal metabolic rate is normal or depressed. The protein-bound iodine concentration ranges from low to high but is most typically in the normal or low range. Characteristically, the butanol extractable iodine is significantly lower than the protein-bound iodine.^{4,5} Radioactive iodine uptake is variable⁶ and ranges from below normal to elevated values, depending on such factors as thyroid-stimulating hormone production by the pituitary, the efficiency of utilization of iodide by the thyroid, and the nature of the component being released into the peripheral circulation.⁷ Plasma albumin is decreased and gamma globulin is elevated. Cephalin flocculation or thymol turbidity tests are abnormal.⁸ The erythrocyte sedimentation rate is usually elevated.

Antibodies to thyroglobulin are present in the serum.^{9,10,11,12} Titers of 80,000 or more are virtually diagnostic of Hashimoto's thyroiditis.¹³ Tanned red cell antibodies are detected in 80 per cent of patients, and with the addition of the complement fixation test, 97 per cent of patients are positive.¹⁴ In young patients, typical Hashimoto's thyroiditis may be present with low titers of antibodies.¹⁵ Thus low titers in this age group do not rule out the disease.

At the Mayo Clinic¹⁶ and Massachusetts General Hospital¹ the most useful approach has proven to be the needle biopsy. The involved thyroid usually has a firmness that makes it relatively easy to biopsy. The whitish plug of tissue is almost diagnostic of Hashimoto's thyroiditis upon gross inspection in a clinically suggestive case.

Pathogenesis

Hashimoto's thyroiditis usually begins as a gradual enlargement of the thyroid gland. It is often discovered by the patient, who find a fullness of the neck or who discovers a new lump while examining himself because of vague discomfort in the neck. Occasionally it is found by a physician during the course of examination for some other complaint.

In some instances thyroid enlargement may be rapid and associated with dyspnea and dysphagia related to pressure on structures in the neck. Occasionally the course is clouded by symptoms of mild thyrotoxicosis, especially during the early phases of the disease. The goiter may remain unchanged for decades¹⁷ but usually increases gradually in size. Symptoms and signs of hypothyroidism commonly develop over a period of years. Eventual thyroid atrophy and myxedema may occur. This assertion is based on the clinical observation that patients with Hashimoto's thyroiditis occasionally develop myxedema, and the knowledge that patients with myxedema due to atrophy of the thyroid have a high incidence of antithyroglobulin antibodies in their serum.¹⁸

The pathophysiology is failure of thyroid cell function resulting in thyroxine deficiency. Apparently, a less calorigenically active thyroglobulin is released, which produces a normal-to-slow increase in protein-bound iodine and is also capable of eliciting an antibody response. This globulin is believed to leak out of cells because of their increased permeability. Later the protein-bound iodine falls as the cells continue to fail. The thyroxine deficiency results in an increase in thyroid-stimulating hormone which may cause a high radioactive iodine uptake. As the ability of the thyroid to trap iodine falls, the radioactive iodine uptake also falls and does not respond to thyroid-stimulating hormone stimulation. Apparently, failure to produce thyroxine occurs before failure to trap iodide. The amount of intrathyroidal exchangeable iodide is abnormally low; therefore, a rapid turnover and high conversion ratio may occur.⁷

The glands of Hashimoto's patients do not bind iodide as efficiently as normal glands.¹⁹ Administration of 400 mg. potassium perchlorate one hour after an I^{131} tracer releases 20 to 60 per cent of the accumulated iodide. There is also evidence of the presence of an abnormal peptide-linked iodinated component.^{3,20,10,21} This is thought to be a distinct iodoprotein rather than a fragment of thyroglobulin.

Buchanan²² has thoroughly studied iodide metabolism in Hashimoto's thyroiditis. He found the I^{131} uptake and clearance rates to be variable.

Plasma inorganic iodide and uptake of stable iodide were normal. The intrathyroidal exchangeable iodine and the efficiency of utilization of trapped iodide by the thyroid both tended to be low. There was also found an increased proportion of plasma organic iodide which was butanol-insoluble.¹⁸

The concept developed from this data is that the diseased gland releases some trapped iodide back to plasma without incorporating it into organic compounds; has a diminished ability to maintain normal thyroid iodide stores; and has a high turnover rate if the exchangeable iodine pool of the gland is low. It also releases non-hormonal organic iodide into the circulation. Because of this inefficient utilization of iodide, the gland is under increased thyroid-stimulating hormone stimulation.

Differential Diagnosis

The differential diagnosis is that of nontoxic nodular goiter. The presence of gross nodularity is against thyroiditis, but not infallible. In nontoxic nodular goiter, function tests are usually normal and hypothyroidism is unusual. Antibody titers are less apt to be high.

Enlargement of thyroid during adolescence¹⁵ is usually due to hyperplasia of thyroid in response to temporarily augmented demand for hormone. Here again function tests should be normal.

Tumor must be considered. The diffuse nature of thyroiditis, the characteristic hypothyroidism, and involvement of the pyramidal lobe are usually sufficient to allow differentiation. Biopsy may prove of little value, since lymphoma or a small-cell carcinoma of the thyroid can be and has been mistaken for Hashimoto's thyroiditis. Lymphosarcoma has been reported in Hashimoto's,^{23,16} and papillary carcinoma has been reported as being associated with the disease.^{16,21} Carcinomas have also been reported in other areas apart from the area of a focal thyroiditis found on biopsy.

Occasionally, Hashimoto's thyroiditis may present as a mild thyrotoxicosis; however, T_3 suppression usually provides the necessary information to make a diagnosis.

Therapy

Many patients need no therapy at all if the disease is asymptomatic and the goiter small; but these patients should be followed for signs of hypothyroidism. Vickery and Ham'in¹⁷ found on serial biopsies that the disease usually remains static for years.

If the gland is of the size to cause pressure symptoms, thyroid hormone usually reduces the size of the goiter over several months.²⁵ In young people with less fibrosis the response has been noted in two to four weeks.

In those cases with rapid development of goiter and pain, steroids have been used both to decrease the inflammatory response and to depress the antibody titer.²⁶

If hypothyroidism is present, replacement therapy with thyroid hormone is mandatory.

Surgery appears to be indicated for pressure symptoms or cosmetic reasons in goiters not responding to medical treatment. It is also indicated in the case of a growing nodule in a young person which does not metabolize I^{31} in a normal fashion.¹ However, if findings suggestive of thyroid carcinoma are not present, medical management with thyroid hormone is the

treatment of choice.

Auto-Immunity

The frequent occurrence of elevated serum levels of gamma globulin, a delay in return to normal levels after thyroidectomy, infiltration of the thyroid substance with lymphocytes and plasma cells, and the not uncommon incidence of Hashimoto's disease with known auto-immune diseases suggest an immune basis for this disease.

Rose and Witebsky²⁷ showed that immunization of rabbits with extracts of their own thyroid tissue produced histologic changes in the thyroid glands resembling those seen in Hashimoto's disease. They also found that antibodies to thyroglobulin could be detected in the blood. Roitt et al.¹¹ observed that a precipitate forms when serum from a patient with Hashimoto's disease reacts with an extract of human thyroid gland. This indicated to them that the serum contained antibodies to a constituent of the human thyroid and that these antibodies might be responsible for the disease process.

Four auto-antigens have been identified in the sera of patients with Hashimoto's thyroiditis. Precipitating antibodies were first identified. With agar gel diffusion or Ouchterlony plate technique they can be demonstrated. Using the tanned red cell hemagglutination test of Boyden²⁸, antibody could be detected at 1/40,000, the titer required to give a positive precipitin reaction. Titers as high as one in five million have been obtained from sera of patients with chronic thyroiditis. Usually a high antithyroglobulin titer of one in 80,000 or more is presumptive evidence of Hashimoto's disease and helps to distinguish it from multinodular goiter and thyroid carcinoma.^{11,12,13} This test is still negative in 10 to 20 per cent of histologically proven cases. So a negative result does not rule out the disease. In ten per cent of women aged 40 to 60, low titers have been found.¹⁵

A second distinct immune system has been identified in patients with Hashimoto's disease. These antibodies fix complement in presence of extracts from thyrotoxic glands and are directed against the microsomal fraction of thyroid cells.²⁹ These same sera have also been shown to have a high cytotoxic activity on trypsinized thyroid cells in tissue culture.³⁰ Whether these antimicrosomal antibodies and the cytotoxic factor are identical has not yet been shown.

The fluorescent antibody technique has been applied to the study of antigen-antibody reaction in the thyroid.³¹ An antibody solution of high titer is conjugated with fluorescein isocyanate, and wherever antigen-antibody precipitates form, the fluorescein-stained complex is fixed and can be localized under a microscope. This method can be used to locate complexes, or as qualitative or quantitative tests. A fluorescein conjugate of the globulin obtained from the serum of patients with Hashimoto's disease reacts not only with normal thyroid, but also with his own gland. This reaction corresponds to the complement-fixing microsomal antibody as shown by the fact that prior absorption of the microsomal fraction inhibits the staining.

In serums of certain patients with Hashimoto's disease, fluorescent antibody technique has also demonstrated a localization of the reaction to the nuclei of the thyroid slice. This is thought to tie in with the frequency of Hashimoto's disease occurring in patients with known immune diseases.

Also using fluorescent antibody techniques an antibody has been seen in the colloid component other than thyroglobulin.

Antithyroglobulin antibodies can be demonstrated by passive cutaneous anaphylaxis technique in guinea pigs.³² Also a skin test has been developed by Buchanan et al.³³; but its use as a routine test is hampered by the risk of serum hepatitis from injection of the extract of thyroid gland.

Several theories have been advanced to explain the auto-immune reactions of Hashimoto's disease. The first involves an abnormality in immune homeostasis in the body, such as failure to properly sequester thyroid antigens from the lymphoid tissue. Evidence for this theory is obtained from the studies of Sommers and Meissner³⁴ who examined the thyroid basement membrane from 70 patients including normal controls, chronic thyroiditis, thyrotoxicosis and thyroid carcinoma. In every instance of thyroiditis there were diffuse abnormalities of the thyroid membrane not only at the location of infiltration but also in remote areas of the gland without infiltrate. In the tissue of the thyrotoxic glands, if there was a lymphocytic infiltrate there were also basement membrane abnormalities. Stuart and Allen³⁵ confirmed the basement membrane lesion in patients with a high circulating antibody level. They found good correlation between the presence of basement membrane lesion and high circulating antibody levels, and no basement membrane lesion in low antibody levels. Although it is an attractive hypothesis that a lesion of the basement membrane precedes and is responsible for the auto-immune process, it is entirely possible that the basement membrane defect is secondary to this process.

The second proposed theory of auto-immunity is a genetically determined capacity for producing auto-antibodies. Support for this theory comes from the association of known auto-immune diseases with thyroiditis. Reports have been published of association between thyroiditis and Sjögren's syndrome,^{34,36} rheumatoid arthritis,³⁷ systemic lupus erythematosus,³⁸ Addison's disease,^{39,40} lipid hepatitis,⁴¹ and portal cirrhosis of the liver in which an identical extensive lymphocytic and plasma cell infiltrate was found in both the liver and the thyroid. In all of the disorders associated with Hashimoto's disease, abnormalities of the immune mechanism have been postulated. Many of the features of these diseases could be explained on the basis of excessive sensitivity of the immune apparatus, resulting in a breakdown in the immune tolerance to the body's own antigens. Such an abnormality of the immune mechanism could possibly result from a genetic defect, as evidenced by the overlap in these diseases, both in the individual and in families.

The third theory proposes an abnormal antigen, which may be either congenital or acquired. Complement fixing and antithyroglobulin antibodies have been found not only in patients with Hashimoto's, but also in their parents

TABLE

and siblings.^{42,43,44} In fact, the disease has been shown in both members of two sets of uniovular twins. It has also been shown that in some patients with Hashimoto's thyroiditis a circulating iodoprotein can be demonstrated similar to that seen in one group of goitrous cretins.⁴⁵ Organification of iodine is sometimes defective in Hashimoto's disease.

Possibly the initial insult to the thyroid results from congenital dysor-monogenesis, a virus infection, thyrotoxicosis, etc. The end picture in each instance would be a nonspecific end of Hashimoto's disease. Since this chain of events does not normally occur in these cases, some overactivity of the immune mechanism would seem to be an additional requisite.

Hennepin County General Hospital Experience

The Table depicts seven cases of Hashimoto's thyroiditis at Hennepin County General Hospital. There were biopsy diagnoses made at surgery on six out of seven cases. The only case not operated had an antithyroglobulin titer of 1:256. Although this is not the diagnostic value reported in the literature, it was significant for the laboratory performing the test.

THE S.S. HOPE is a floating medical center — a fully staffed and fully equipped modern hospital which is the vehicle by which Project HOPE fulfills its mission of carrying American medical treatment and training to foreign lands where such help is not only needed but wanted. Project HOPE is a nongovernmental, nonprofit organization which is financed solely by voluntary contributions from individuals and private enterprise of North America.

THEIR HOPE — Although thousands of natives are treated on ship and ashore, the primary objective of HOPE is teaching. Every HOPE physician, nurse, or technician has his local counterpart who is trained to continue modern treatment after the ship leaves. It is a seeding process which multiplies in the underdeveloped country to improve the health of its citizens and thus their productivity and thereby creates a progressive economy and a higher living standard. The kind of economy in which communism cannot thrive!

OUR HOPE — HOPE — an acronym for Health Opportunities for People Everywhere — is a young Project only in its fourth year of operation but already the evidence is incontestable that its missions are highly successful, not only in the interchange of medical knowledge but also in promoting international friendship and goodwill.

YOUR HOPE — HOPE's basic professional staff of nurses, technicians, etc., are paid a nominal salary but most of its teaching physicians and dentists serve without financial compensation. This makes it not only our most successful foreign aid program but also our cheapest. Nevertheless, private contributions are essential. You may participate by drawing and mailing a check to:

Dulcolax[®]

bisacodyl

DU-5255 R

Few drugs work as predictably as Dulcolax. You can expect that when your office patient takes Dulcolax at home, it will be as effective as you said it would be. Your patient will be gratified, too.

The reliability of Dulcolax stems from its unique mode of action. The drug works directly on nerve endings in the colonic mucosa, producing normal peristalsis throughout the large intestine. It does not rely on systemic absorption for its effect.

This reliable action provides prompt relief of constipation. It also makes Dulcolax par-

ticularly useful for prepping the bowel for special procedures. In short, it makes Dulcolax ideal for your office practice.

Dulcolax acts so surely that the time of evacuation can often be closely predicted. Dulcolax tablets taken at night almost invariably result in a bowel movement soon after waking the following morning. Dulcolax suppositories generally work in 15 to 20 minutes, almost always within the hour.

General Dosage Information: *Adults:* When an ordinary laxative effect is desired, 1 to 3 tablets or 1 suppository usually suffices. Tablets must be swallowed whole, not chewed or crushed, and should not be taken within one hour of antacids or milk. *Children:* 1 or 2 tablets, depending on age and severity of condition. Tablets must not be given to a child too young to swallow them whole. For infants and children under 2 years of age, half a suppository is usually effective. Above this age a whole suppository is usually advisable. **Side Effects:** As with any laxative, abdominal cramps are occasionally noted, particularly in

severely constipated persons. High dosage may result in loose, unformed stools. **Contraindication:** Contraindicated only in acute surgical abdomen. **Availability:** Tablets (5 mg.) and suppositories (10 mg.). By prescription or recommendation.

- Despite introduction of synthetic substitutes, efficacy of 'Empirin' Compound with Codeine remains unchallenged.

BURROUGHS WELLCOME & CO. (U.S.A.) INC., Tuckahoe, N.Y.

When the talk turns to oral contraceptives, it makes medical sense to remember low-dose Norinyl-1.

(norethindrone 1mg $\bar{c}$ mestranol 0.05mg)

Turn page for contraindications, precautions and side effects.

Reduction of oral contraceptive dosage to the lowest effective levels is a well-accepted principle of conservative medical practice. In keeping with this view, Norinyl is now also available as Norinyl-1, containing exactly one half the previous dosage of norethindrone and mestranol. Clinical experience has established that effective fertility control can be achieved with the same degree of reliability and safety with new Norinyl-1 when taken as directed.

What about switching patients from higher dosage forms?

In transferring patients to low-dose Norinyl-1 from higher-dosage oral contraceptives, some breakthrough bleeding may occur in the early cycles. In the majority of cases the bleeding episode is mild and self-limited. The long-term advantages of the lower dosage form should be weighed against the inconvenience of possible breakthrough bleeding in the individual patient.

Prescribing Information

Contraindications: Patients with any symptoms or history of thrombophlebitis, pulmonary embolism, liver dysfunction or disease, carcinoma of breast or genital organs, or undiagnosed vaginal bleeding.

Warnings: Discontinue medication pending examination if there is sudden partial or complete loss of vision, proptosis, diplopia or migraine. If examination reveals papilledema or retinal vascular lesions, medication should be withdrawn. The safety of Norinyl-1 in pregnancy has not been demonstrated. If a patient misses two consecutive periods, pregnancy should be ruled out before continuing the medication. If she has not adhered to the prescribed schedule, pregnancy should be considered at the first missed period. Active ingredients of oral contraceptives have been detected in the milk of mothers who received these drugs; the significance to infants has not been determined.

Precautions: Pretreatment physical should include examination of the breasts and pelvic organs, as well as a Papanicolaou smear. If endocrine or liver function tests are abnormal during therapy, repeat tests are recommended after the drug has been withdrawn for two months. Following administration of drug, preexisting uterine fibromyomata may increase in size. Careful observation and caution are required for patients with symptoms or history of epilepsy, migraine, asthma, cardiac or renal dysfunction, cerebrovascular accident, psychic depression, and diabetes. In cases of undiagnosed vaginal bleeding, adequate diagnostic measures are indicated. Possible long-term effects of the drug on pituitary, ovarian, adrenal, hepatic or uterine function must await further studies. The physician should be alert to the earliest manifestations of thrombophlebitis and pulmonary embolism. The drug should be used judiciously in those young patients in whom bone growth is not complete. The age of the patient constitutes no absolute limiting factor, although treatment with Norinyl-1 may mask symptoms of the climacteric. The pathologist should be advised of Norinyl-1 therapy when relevant specimens are submitted.

Side Effects: The following have been observed with varying incidence in patients receiving oral contraceptives: nausea, vomiting, gastrointestinal symptoms, breakthrough bleeding, spotting, change in menstrual flow, amenorrhea, edema, chloasma or melasma, breast changes (tenderness, enlargement and secretion), change in weight (increase or decrease), changes in cervical erosion and cervical secretions, suppression of lactation when given immediately postpartum, cholestatic jaundice, migraine, rash (allergic), rise in blood pressure in susceptible individuals, mental depression. Although the following side effects have been reported in users of oral contraceptives, no cause and effect relationship has been established: anovulation posttreatment, premenstruallike syndrome, changes in libido, changes in appetite, cystitis-like syndrome, headache, nervousness, dizziness, fatigue, backache, hirsutism, loss of scalp hair, erythema multiforme, erythema nodosum, hemorrhagic eruption, and itching. The following occurrences have been observed in users of oral contraceptives (a cause and effect relationship has neither been established nor disproved): thrombophlebitis, pulmonary embolism, neuroocular lesions.

The following laboratory tests may be altered by the use of oral contraceptives: increased sulfobromophthalein and other hepatic function tests, coagulation tests (increase in prothrombin, factors VII, VIII, IX and X), thyroid function (increase in PBI and butanol extractable protein-bound iodine and decrease in T^3 values), metyrapone test, pregnanediol determination.

norethindrone — an original steroid from
SYNTEX 
LABORATORIES INC., PALO ALTO, CALIF.

Here's why Norinyl-1 makes medical sense.

The effectiveness of Norinyl-1 as a low-dose oral contraceptive may be explained by its possible multiple action. In addition to its primary action of suppression of ovulation, Norinyl-1 may offer additional protective mechanisms... (1) creation of a cervical mucus that may be hostile to sperm penetration, and (2) development of an endometrium that may be out of phase with nidation.

These effects are illustrated below.

Untreated Patient

Cervical mucus at midcycle is usually thin and watery, with Spinnbarkeit (stretchability) of 15 to 20 cm.

Spermatozoa appear healthy, active, freemoving.

Endometrium of untreated patient is receptive to the fertilized ovum during secretory phase.

Norinyl-1 Patient

Cervical mucus at midcycle is scanty, viscous—with Spinnbarkeit of 1 cm. or less.

Immobile spermatozoa as they appear in cervical mucus taken from patient treated with Norinyl-1.

Norethindrone in Norinyl-1 accelerates secretory phase, suppresses glandular and vascular development.

Norinyl-1
(norethindrone 1mg. & mestranol 0.05mg.) tablets

- new low dose of time-proved ingredients
- established norethindrone/mestranol ratio
- lower patient cost

An uncommon steroid for common inflammatory dermatoses

In everyday topical steroid therapy, Synalar produces rapid resolution of inflammation and itching in steroid-responsive dermatoses—and at relatively low cost to the patient.

Advanced molecular design enhances potency

Synalar combines the advantage of earlier corticosteroid compounds with unique structural innovations. As a result, preparations of Synalar 0.01% and Synalar 0.025% have been reported to be more potent topically and significantly more effective than hydro-

cortisone 1.0%. The unique fluocinolone acetonide molecule provides one of the most useful topical corticosteroids for everyday practice.

Impressive clinical results in a wide range of dermatologic problems

The clinical efficacy of Synalar has been extensively documented in the world literature. Commonly encountered diseases such as allergic and contact dermatitis, eczematous and seborrheic dermatitis, and neurodermatitis respond rapidly to Synalar, often

where previous therapy with other topical corticosteroids has failed.

Low patient cost for wider usefulness

With Synalar, a high degree of efficacy does not mean high price. And—a small quantity goes a long way. Thus, your patients can often obtain the “economy” of a hydrocortisone preparation with the proved efficacy of a potent, truly advanced steroid.

Synalar[®]
fluocinolone acetonide

Turn page for contraindications, precautions and side effects.

For everyday topical steroid therapy

Synalar® 0.01%

fluocinolone acetonide

provides economy in two practical dosage forms

For general use, the most economical and widely applicable concentration of Synalar is 0.01% Cream in a water-washable, vanishing cream base. Synalar Solution 0.01% is especially valuable in dermatoses involving moist, intertriginous areas or hairy sites where creams and ointments do not spread or penetrate readily. Synalar Solution is a unique dosage form—clear, nongreasy, cosmetically elegant.

Product Information

Contraindications: Tuberculous, fungal, and most viral lesions of the skin (including herpes simplex, vaccinia, and varicella). Not for ophthalmic use. Contraindicated in individuals with a history of hypersensitivity to any of the components.

Precautions: Synalar preparations are virtually nonsensitizing and nonirritating. However, the solution may produce burning or stinging when applied to denuded or fissured areas. In some patients with dry lesions, the solution may increase dryness, scaling or itching. Where severe local infection or systemic infection exists, the use of systemic antibiotics should be considered, based on susceptibility testing. While topical steroids have not been reported to have an adverse effect on pregnancy, the safety of their use on pregnant females has not absolutely been established. Therefore, they should not be used extensively on pregnant patients, in large amounts, or for

prolonged periods of time. **Side Effects:** Side effects are uncommon with topical corticosteroids. As with all drugs, however, a few patients may react unfavorably to Synalar under certain conditions. In such cases the agent should be discontinued and appropriate measures taken.

Availability: Synalar (fluocinolone acetonide) Cream 0.025%—5, 15 and 60 Gm. tubes and 425 Gm. jars. Cream 0.01%—15, 45 and 60 Gm. tubes and 120 Gm. jars. Solution 0.01%—20 and 60 cc. plastic squeeze bottles. Ointment 0.025%—15 and 60 Gm. tubes. Neo-Synalar® (neomycin sulfate 0.5% [0.35% neomycin base], fluocinolone acetonide 0.025%) Cream—5, 15 and 60 Gm. tubes.

Dear Doctor:

Wouldn't you like your patients to learn more about the contributions made by the world of medicine to their welfare? So that they can better appreciate the efforts of the health team to keep them in good health?

To tell the stories of medical and pharmaceutical advances to people throughout the country, the Pharmaceutical Manufacturers Association is sponsoring a unique "magazine within a magazine." It is called *Medicines and your family's health* and the first issue appears in the November *Reader's Digest*.

We would like to send you 50 free reprints of *Medicines and your family's health* for use in your reception room. Your patients will find the articles in this issue factual, educational and of immediate personal interest.

Just fill out the coupon below and send it to us.

ISOTOPES AS A DIAGNOSTIC TOOL*

The use of radioisotopes, or more properly radionuclides, as medical diagnostic agents, is undergoing a rapid evolution at the present time, particularly in the field of organ and tumor visualization. There is a growing appreciation of the array of complex factors which govern the retrieval of information from the various isotope distributions which occur in the body following the administration of radiopharmaceuticals. More sophisticated equipment, radiation sources which produce relatively little radiation dosage to the patient, and a variety of new radiopharmaceutical agents have given rise to an increase in available counting rates by a factor of a hundred or more in some cases. In particular the use of short-lived isotope generators, multiple head scanners and camera type detectors appears to be growing in many institutions. Future developments with spark chambers, avalanche chambers, image intensifiers and multiscanner configuration devices with sophisticated image-processing techniques developed to some extent in connection with space age projects hold much promise. The need for production of very short-lived radionuclides has led to the design and construction of small, relatively inexpensive reactors and cyclotrons for on-site use.

BELOW-KNEE AMPUTATION FOR ISCHEMIC GANGRENE

Fifty-five below-knee amputations were performed in 53 patients with far advanced ischemia of the lower extremity with a success rate of 83% in the 45 patients who survived the surgery. Twenty-eight of the 36 patients whose wounds healed successfully were rehabilitated with a prosthesis.

Important points in technique stressed by the authors were: (1) Circular skin incision to insure maximum chance for skin viability and (2) atraumatic handling of the tissue with guillotine division of the muscles.

The authors feel that if the profunda femoris artery is patent there will be sufficient collateral circulation to permit below-knee amputation. All of their

patients had good flow in the profunda femoris artery. They do not feel that flow through the superficial femoral and into the popliteal artery is necessary for a successful outcome.

Comment: The points in technique stressed in this article are commendable and it does seem reasonable that, with present day refinements in surgery, anaesthesia, and ancillary services, the risk of a second higher amputation should in a good many cases be taken in order to better rehabilitate a significant number of patients.

Harrison H. Farley, M.D.
Minneapolis, Minnesota

Lim, Robert C., Jr. et al.: Below-Knee Amputation for Ischemic Gangrene. Surg Gynec Obstet 125:3:493, 1967.

LIMB SALVAGE IN DIABETICS WITH "HOPELESS ISCHEMIA"

The author reports on thirteen diabetic patients who underwent fifteen reconstructive vascular procedures to attempt salvage of limbs with extreme ischemia, eminent gangrene, or localized gangrene progressing towards "total tissue death." The common denominator for these cases was the tissue damage plus an extremely poor arterial runoff below the knee. One patient died post-operatively of a myocardial infarction. This patient was seventy-two years old and represents a mortality of 6.6%. Three of the remaining fourteen limbs subsequently required amputation.

Comment: This type of procedure can be done with as low a mortality as a limb amputation because, although the operating time is admittedly longer, the tissue disruption is much less. Reconstructive vascular procedures utilizing autogenous vein tissue and careful detailed technique can salvage limbs now which would have been amputated ten years ago. The sole question would seem to be whether the patient needs the limb for mobilization; for to salvage a limb that may still require special care in a bedridden patient on the basis of "morale boosting" hardly seems justified.

Harrison H. Farley, M.D.
Minneapolis, Minnesota

Alderman, O. B.: Limb Salvage in Diabetics with "Hopeless Ischemia." JAMA 201:4, 1967.

John Hunter as a Boy

A dullard at books, he knew more about ants, birds, bees, tadpoles, and worms than anyone in the neighborhood. He never tired of watching them, and to learn more about what they were like he cut them open. What he could not find by himself he tried to learn by questioning everyone: Why do leaves turn yellow and red in the autumn? Why do clouds take different shapes? What makes grass grow where it isn't planted? He would stop the farmhands at their work and ply them with questions: Why does milk dry up in the cow's udder when her calf is taken away? Why does a fierce bull become a docile ox after it is gelded? Not knowing the answers, nor even wanting to know, the farmers thought John a nuisance. And his parents were sure that no good could possibly come from this idle foolishness, which showed no signs of abating as he grew older.*

*Sarah R. Riedman: Masters of the Scalpel, 1962.

Book Reviews

Educate your children to self-control, to the habit of holding passion and prejudice, and evil tendencies subject to an upright and reasoning will, and you have done much to abolish misery from their future lives and crimes from society. Knowledge does not comprise all which is contained in the large term of education. The feelings are to be disciplined; the passions are to be restrained; true and worthy motives are to be inspired; a profound religious feeling is to be instilled, and pure morality inculcated under all circumstances. All this is comprised in education.—Daniel Webster.

THE THYMUS: EXPERIMENTAL AND CLINICAL STUDIES—A Ciba Medical Foundation Symposium. G. E. W. Wolstenholme and Ruth Porter, editors. Little Brown and Company, Boston, Massachusetts, 1966, 538 pages, \$15.00.

This book represents a collection of papers read at a symposium in Melbourne, Australia, on August 25 through 27, 1965, in honor of Sir Macfarlane Burnet. It includes monographs in the general fields of (1) the structure and development of the thymus, (2) the function of the lymphocyte, (3) the role of the thymus and cellular and humoral immunity, (4) the role of the thymus in leukemogenesis and carcinogenesis, and (5) auto-immune disease of the thymus: experimental and clinical studies. Most papers are followed by discussions. Illustrations and references are adequate.

The participants in this international symposium included many of the well recognized scholars in the field of immunology, and consequently most of the papers presented are quite detailed. This book will be of considerable interest to the physician primarily interested in immunology but will probably not be of much use to the practicing physician.

Gerald Onstad, M.D.
Hennepin County General Hospital

DERMATOPATHOLOGY, by Hamilton Montgomery, 1320 pp., 1777 illustrations (58 in color), \$60, New York, Hoeber Medical Division, Harper & Row, 1967.

Rarely out of the maw of the medical press comes a classic. When I call *Dermatopathology* a classic, I mean it is an authoritative work of such excellence that it will endure.

Hamilton Montgomery, emeritus consultant and emeritus professor in the section of dermatopathology at the Mayo Clinic, has studied the skin since 1918. He leaned toward skin diseases naturally, for his father was a dermatologist. With Ormsby, the older Montgomery wrote *Diseases of the Skin*, a well-known textbook now

in its eighth edition. Eventually the son replaced his father as that book's coauthor and went on to become an international authority in his field.

He prefaces his book with the remark that he put it together for "those who are interested in dermatopathology in its broadest aspects." This audience, he adds, includes not only dermatologists and pathologists, but clinicians who want to understand skin changes in systemic disease, research workers who seek investigative details, and students who wish to ground themselves in fundamentals of dermatology.

Doctor Montgomery prescribes a tall order for himself. How does he carry it out? After he introduces the book and gives a chapter on biopsy, he has his colleague, Richard K. Winkleman, a professor of dermatology, write two sections—Histochemistry of the Skin and Normal Structure of the Skin. Once Doctor Winkleman tells what skin is and how to prepare and stain it, Doctor Montgomery proceeds with the next 34 chapters.

To portray the contents briefly is difficult. Chapters begin with congenital dysplasias and end with metastatic cutaneous neoplasms. Between these extremes, the author describes and illustrates about everything that can happen to the skin. With each lesion or group of lesions he defines terms, sketches historical background, clarifies pathological features, and sets forth relevant facts on diagnosis and pathogenesis. He writes clearly and, when he discusses controversial topics, he does not hesitate to tell where he stands.

While Doctor Montgomery's discussions are excellent, what distinguishes *Dermatopathology* are its 1777 illustrations. He has assembled a vivid array of photomicrographs, and his 58 color plates are among the best I have seen. Readers who know the expense of colored reproductions will appreciate why the book costs \$60. This handsomely bound and beautifully produced two-volume set will occupy a prominent place in the libraries of dermatologists and pathologists.

Richard L. Reece, M.D.
Minneapolis, Minnesota

"George wants to know if it's okay to take his cold medicine now, Doctor, instead of seven o'clock?"

The long-continued action of Novahistine LP should help you both get a good night's sleep. Two tablets in the morning and two in the evening will usually provide round-the-clock relief by helping clear congested air passages for freer breathing. Novahistine LP also helps restore normal mucus secretion and ciliary activity—normal physiologic defenses against infection of the respiratory tract. Use cautiously in individuals with severe hypertension, diabetes mellitus, hyperthyroidism or urinary retention. Caution ambulatory patients that drowsiness may result. Each Novahistine LP tablet contains: phenylephrine hydrochloride, 25 mg., and chlorpheniramine maleate, 4 mg.

NOVAHISTINE[®] LP

PITMAN-MOORE Division of The Dow Chemical Company, Indianapolis

Sustained circulatory, respiratory and cerebral stimulation for the

(fewer absent doses by
absent-minded patients)

Human volunteer subjects were administered Geroniazol TT tablets with the nicotinic acid component made radioactive with C-14. Plasma and urine samples were analyzed. (See Figures I and II) The radioactive tracer study substantiated the previous clinical evidence that the release of nicotinic acid from the Geroniazol TT tablet produced a gradual rise in plasma levels to a plateau for a total of 12 hours and more.

Such proven sustained activity makes the management of geriatric patients much easier by minimizing the possibility of neglected doses through absent-

mindedness or senile confusion. Therapy *can* be continuous on a daily dose of only one Geroniazol TT tablet every 12 hours.

The gradual release of nicotinic acid in Geroniazol TT will provide the well-known peripheral vasodilation needed in patients with deficient circulation and with a minimum amount (if any) of "flushing." Also, cerebrovascular circulation is complemented by pentylentetrazol, long-established as a cerebral and respiratory stimulant.

Geroniazol TT improves the typical, unfortunate, signs of senile confusion. Patients become more alert,

aged and debilitated

less confused and moody. Personal care, memory, emotional stability, social attention improve. Fatigue, apathy and irritability are reduced.

A prescription for 100 tablets of Geroniazol TT will permit your patients to enjoy the benefits of time-prolonged nicotinic acid/pentylentetrazol therapy, at an economical price. Dosage is only one tablet every 12 hours.

Contraindications: There are no known contraindications.

Precautions: Exercise caution when treating patients with a low convulsive threshold.

Side Effects: Side effects are rarely encountered, however due to the vasodilatation effect of nicotinic acid, transitory mild nausea, flushing, tingling and pruritus are possible.

Dosage: One tablet every 12 hours.

Supplied: Prescribe bottles of 100 tablets, to take advantage of recent price reduction.

Serum Creatine Phosphokinase as a Diagnostic Aid

A

Review*

DANIEL J. LOEGERING, M.A.**
JERRY B. CRITZ, Ph.D.**
JEAMES A. WAGNER, M.A.**

London, Ontario

SERUM ENZYMES have now been used for years to diagnose diseases. Serum creatine phosphokinase is one of these enzymes, but it was not introduced into the United States until 1962.¹

Creatine phosphokinase catalyzes the reversible transfer of a high energy phosphate group from adenosine triphosphate to creatine as follows:

The reaction can be made to proceed in either direction by adding appropriate substrates. Creatine phosphate hydrolyzes to creatine and inorganic phosphate, and the phosphate is then measured colorimetrically.² If the reverse reaction is used, creatine is determined, also with a colorimeter.^{3,4}

Some feel assays of inorganic phosphate and creatine are not as reliable as techniques which measure adenosine diphosphate or adenosine triphosphate.⁵ However, determinations of these are more difficult because they link adenosine triphosphate and adenosine diphosphate to secondary enzyme systems which convert DPNH to DPN or TPNH to TPNH. The change of optical density in the reaction systems determines the activity of creatine phosphokinase.^{6,7}

Creatine phosphokinase is an excellent enzyme for testing because of its distribution. It is concentrated in skeletal and heart muscle and, to a lesser extent, in brain tissue. It cannot be detected in red cells, liver, or kidney.⁸ Because of this distribution, an increase in serum creatine phosphokinase usually indicates skeletal muscle or heart damage, and lack of activity eliminates in red blood cells the problem of hemolysis (Table 1).⁹

Muscular Dystrophy

Patients with muscular dystrophy have ele-

*Supported in part by Grant AM 06154, National Institute of Health, USPHS.

**The Department of Physiology, University of Western Ontario Faculty of Medicine, London, Ontario, Canada.

vated levels of several enzymes. These include aldolase,¹⁰ the transaminases,^{11,12} lactic dehydrogenase, and malate dehydrogenase. In 1959 Ebashi and his coworkers discovered that patients with progressive muscular dystrophy also had elevated serum creatine phosphokinase.¹³ Studies also showed that serum creatine phosphokinase surpassed other enzymes in diagnosing dystrophy¹⁴ and also helped to separate the Duchenne type of dystrophy from other forms.¹⁵

**Relative activity referred to serum as unity.

The Duchenne type, the most severe, causes the greatest rise in serum creatine phosphokinase;¹⁷ and younger patients, who have had the disease for the shortest time, show the highest levels. In other inherited myopathies, the enzyme goes up, but much less than in patients with the Duchenne type. In the dystrophies, severity of the disease correlates well with serum creatine phosphokinase levels (Table 2).¹⁶ Furthermore, levels increase in preclinical cases of Duchenne dystrophy, especially in young patients with a family history of dystrophy.¹⁸

TABLE 2
Serum CPK Activity in Different Types of Muscular Dystrophy

Type	Mean SCPK ¹⁶
Duchenne type	373 I.U.
Lim-girdle type	26 I.U.
Fascioscapulohumeral type	10 I.U.
Upper limit of normal	3.5 I.U.

The age at which the sample is taken must be kept in mind, for serum creatine phosphokinase decreases as patients with Duchenne's dystrophy grow older (Figure 1).^{16,19} Duchenne dystrophy could be diagnosed as the limb-girdle type if the patient is not tested at the

proper time. Enzyme decrease may be due to loss of functional muscle mass;^{16,19} but Stephens and Lewin report that decrease of serum enzyme activity may be due to the lack of activity of the patient as the disease reaches its final stages.²⁰

Acquired Myopathies

Acquired myopathies or muscular atrophy of neurogenic origin seldom cause a rise in serum creatine phosphokinase. Dermatomyositis,⁸ polymyositis,¹⁶ and denervation¹⁹ occasionally produce elevation; but poliomyelitis, polynuritis, myasthenia gravis,²¹ anterior horn diseases, and peripheral nerve diseases⁸ do not.

Duchenne Muscular Dystrophy Carriers

Some carriers of Duchenne dystrophy have elevated serum creatine phosphokinase. Studies indicate that 70 to 80 percent of known carriers have levels of one to four times normal.^{18,22,23} Known carriers are those with a family history of dystrophy and are parents of dystrophic children. Creatine phosphokinase values vary in these carriers, but they are more consistently increased than with other serum enzymes. Brugsch and his associates were unable to detect carriers with lactic dehydrogenase, glutamic-oxalacetic transaminase, and glutamic-pyruvic transaminase tests, although a few carriers showed elevated serum aldolase.²⁴ Pearce, Pennington, and Walton tested female relatives of patients with Duchenne dystrophy and concluded that serum creatine phosphokinase offered a sound basis for genetic counseling.¹⁸ Carriers apparently have isolated dystrophic muscle fibers, which may be responsible for the elevated serum creatine phosphokinase. These fibers later disappear, giving normal levels even in known carriers.²⁰

Stephens and Lewin say that physically active carriers may have higher enzyme levels.²⁰ In four carriers, 10 hours of bed rest reduced serum creatine phosphokinase to normal; yet when they exercised, enzyme activity rose promptly. This phenomenon did not occur in normal subjects. The authors suggested that the enzyme leaked through the abnormal muscle membrane when carriers exercised.²⁰

Myocardial Infarction

Because creatine phosphokinase is concen-

trated in the myocardium, serum levels rise when heart damage occurs. Dreyfus *et al.* first illustrated this in 1960,⁴⁹ and many have since confirmed it. Precisely what per cent of patients with known infarcts have elevated serum creatine phosphokinases remains unknown. But to date almost all patients tested have shown an increase. Of 93 patients reported in two studies,^{26,27} only one failed to have an increase after an infarction.

Serum creatine phosphokinase and glutamic-oxalacetic transaminase remain high for about the same time span after an infarction. Both first increase about six hours after symptoms start, peak at 24 to 48 hours, and return to normal after three or four days (Figure 2)²⁷⁻³⁰. Creatine phosphokinase increases relatively more than transaminase. While transaminase may go up to 12 times its normal level, creatine phosphokinase can exceed 40 times its usual range.

Whether peak values of serum creatine phosphokinase can be used to forecast prognosis or whether they reflect the size of infarcts is not yet certain. However, Sorenson found that patients who had high creatine phosphokinases at 48 hours fared more poorly than patients whose phosphokinase returned to normal in that time¹⁶; and Muller ligated coronary arteries in dogs, measured the infarct size, and found that serum creatine phosphokinase correlated well with the extent of necrosis.³⁰

Compared to other serum enzyme tests which increase in myocardial necrosis, creatine phosphokinase is more specific. In a patient with typical symptoms of infarction, Warburton *et al.* go so far as to say that an elevated level 48 to 72 hours after the attack is diagnostic of myocardial infarction.²⁸ It is superior to serum glutamic oxalacetic transaminase and aldolase because these relatively nonspecific enzymes may rise in shock, probably because of slight liver necrosis²⁹. In terms of specificity, serum creatine phosphokinase compares well even with lactic dehydrogenase isozymes. Alpha-hydroxybutyric dehydrogenase, an isozyme of lactic dehydrogenase specific for heart muscle, is not wholly satisfactory for diagnosing infarction. Lactic dehydrogenase isozymes can yield similar or identical patterns in patients with myocardial infarction, infarcts of the kidney, pernicious anemia, lymphomas with

hemolytic anemias, or progressive muscular dystrophy³¹.

Cerebral Infarction

Brain tissue has a creatine phosphokinase concentration slightly more than half that of heart muscle. Acheson has reported that 15 to 24 patients with acute cerebrovascular accidents

Fig. 1—The relation between serum levels of creatine phosphokinase and the age of patients with the Duchenne type of muscular dystrophy. (From Pearce, Pennington, and Walton, 1964¹⁷; and Hughes, 1963²⁰.)

Fig. 2—The time course of serum creatine phosphokinase and serum glutamic oxalacetic transaminase activity of a single patient with a severe acute myocardial infarction. The upper limit of the normal range for each enzyme is indicated on the ordinate by ULN. (From Vincent and Rapport, 1965²⁸.)

had elevated serum levels.³² Levels peaked in four days and returned to normal in eight days. Four of the five patients who died had levels seven times normal. Thus, in patients who died, the higher the level, the worse the prognosis. In those who survived, the level apparently had little to do with the severity of brain damage.

Other Diseases

Since creatine phosphokinase is absent from the liver, it does not rise in liver disease. This is perhaps its greatest advantage over other enzyme tests. In fact, when used with other enzymes, its very absence can help pinpoint the liver as a source of trouble. For example, in congestive failure, as the liver becomes congested, transaminase levels will climb, but serum creatine phosphokinase remains normal.²⁹

Muscle trauma, including surgery, will increase creatine phosphokinase activity. The level depends on the extent of injury. A two to five-fold increase was found 24 hours after major surgery in five patients, but a single patient with basal cell carcinomas who had them excised had no rise.²⁴ Frequent intramuscular injections of irritating drugs, such as aqueous penicillin, can elevate creatine phosphokinase four to five times, but occasional injections of narcotics, diuretics and barbiturates do not appear to influence the level.¹ Patients with hemorrhagic pancreatitis involving the abdominal muscles also have high levels.³⁴

Because creatine phosphokinase is specific for myocardial necrosis, it can be used to exclude other diseases with similar symptoms. Myocarditis may mildly increase serum creatine phosphokinase, but only if it produces ischemic necrosis.²⁹ Angina pectoris,³⁵ pericarditis,²⁹ coronary insufficiency, cardiac arrhythmia,²⁷ tachycardia, and arteriosclerotic hypertensive heart disease²⁶ usually show normal levels.

Pulmonary embolism or pulmonary infarction do not generally boost serum creatine phosphokinase levels.^{26,27} However, Velez-Garica *et al.*, using Fiske and Subbarow's method, found that 13 of 33 patients with pulmonary disease showed increased phosphokinases. None of these patients had electrocardiographic evidence of myocardial infarction; but

the 13 with increased levels all had severe acute pulmonary disease. The authors felt that damaged lung tissue might release the enzyme, but they added that anoxic or edematous skeletal muscle was a more likely source. Velez-Garica and his associates also point out that patients with diabetic acidosis and intoxicated chronic alcoholics have increased levels.³⁴

Hypothyroidism

In hypothyroidism, serum creatine phosphokinase values may go up two to five times normal. When patients are treated, the level returns to normal in three to four weeks and remains normal as long as the patients are euthyroid. No one has explained this satisfactorily, though many have commented on it.³⁶⁻³⁹

Non-Disease States

Generally, only prolonged exercise will increase serum levels. Short-term exercise has no effect: for example, rapidly climbing 70 stairs or a brisk four-mile walk.^{23,40} A two-hour run will cause a three-fold increase, a 25-mile walk a seven-fold increase, and a 53-mile walk a 24-fold increase.^{40,41} Intense physical labor for two days will also result in a rise.⁴¹ In our laboratory a large number of dogs running on a treadmill at 10 miles per hour for one hour demonstrated a large increase in serum creatine phosphokinase activity (43 Im U/ml increased to 250 Im U/ml, unpublished dissertation). Griffiths found that the normal range of creatine phosphokinase differs in active and resting people.⁴¹ Rat studies support this. Kindrick-Jones and Perry report that confined rats had creatine phosphokinase activities lower (283 units) than non-confined control rats (497 units).⁴³

During pregnancy, serum creatine phosphokinase remains stable.^{37,43} At delivery and for one to two days after, enzyme levels increase up to three times normal.^{44,45} This is believed to be due to loss of creatine phosphokinase from the uterus as it involutes.^{44,46} According to Emery and Pascasio, the involuting uterus loses 3300 units of enzyme during the first two postpartum days.⁴⁴

Reports vary concerning the effect of age and sex on the serum level of creatine phosphokinase. Newborns have a serum level two

to three times adult levels, and it remains elevated for from one to ten years.^{40,48} Then the level remains constant through adult life. Men and women differ little in their creatine phosphokinase levels although some investigators report a slightly higher level in men.⁴⁹

Summary

Creatine phosphokinase, an enzyme concentrated mostly in the myocardium and in skeletal muscle, increases in the serum when dystrophy or myocardial infarction occurs. In dystrophy, levels are especially high early in

the disease and descend as the disease progresses and muscle mass is destroyed. Carriers of the disease tend to have higher levels than normal. For diagnosing myocardial infarction, the enzyme may be better than the serum glutamic-oxalacetic transaminase. It reaches relatively higher levels and, because of its absence from the liver, does not increase with liver congestion as the transaminase sometimes does. Other conditions which can cause serum creatine phosphokinase elevations include cerebral infarction, hypothyroidism, violent exercise, major surgery, and involution of the uterus after delivery.

Irido-Diagnosis

The poetical notion that the eye is the mirror of the soul evidently convinced a minor medical prophet in Chicago that money might be made by founding a school of medicine in which the diagnosis of all diseases would depend on the ability to notice the changing colors of the iris or colored material of the eye. With a remarkable genius for publicity, he succeeded in attracting much free newspaper mention and in leading to his school numerous ignorant satellites who desired to enter on the practice of healing by some easy route. Among those attracted have been a few regularly licensed physicians who sought to exploit themselves and enhance their incomes by adding the claim of this superior power to such as might already have been conferred upon them by the state. Even today the practitioners of this vagary burst into temporary luminescence in the sensation-seeking press. Fortunately the prophet himself was accused by his wife of mental vagaries. He gradually subsided!*

Man should go out of this world as he came in—chiefly on milk.

—William Osler

She doesn't feel she "suffers" from hypertension

**Butiserpazide® lowers blood pressure
so smoothly that patients are often untroubled
by either disease *or* therapy**

By switching patients to BUTISERPAZIDE you may be able to free them of much of the burden of hypertension. Clinical comparisons have shown that many respond with (1) smooth, uniform lowering of blood pressure¹...at times to levels *below* those attained with previous therapy²; (2) "striking" improvement in such symptoms as headache, nervousness, palpitation and dizziness²; plus

(3) "...lowered incidence of drug side effects."²

And there's an added advantage: the usual dosage is just 1 tablet once or twice daily, often without need for supplementary therapy. (BUTISERPAZIDE provides not only hypotensive and diuretic action, but a mildly sedative effect as well.) Isn't this the way to take the suffering out of hypertension?

You have a choice of 2 strengths:

Butiserpazide®-25

Prestabs®* Tablets

BUTISOL® (butabarbital) 30 mg. (½ gr.)†;
Hydrochlorothiazide 25 mg. (¾ gr.); Reserpine 0.1 mg.

in mild to moderate cases, often effective at half the usual thiazide or thiazide/reserpine dosage.

Butiserpazide®-50

Prestabs®* Tablets

BUTISOL® (butabarbital) 30 mg. (½ gr.)†;
Hydrochlorothiazide 50 mg. (¾ gr.); Reserpine 0.1 mg.

controls many moderate to severe cases without any need for ganglionic blockers, or other more potent agents; if such agents are needed, their dosage can be cut in half.

*15 mg. of Butisol (butabarbital), plus the other ingredients, in outer layer; 15 mg. of Butisol (butabarbital) in a specially coated core for delayed action, to approximately equalize duration of action for all components.

Contraindicated in presence of renal impairment, peptic ulcer, ulcerative colitis, or mental depression, and in patients with porphyria or those sensitive to any component. **Warning:** Coated potassium tablets, sometimes administered in conjunction with anti-hypertensive therapy, may be associated with small bowel lesions which have led to obstruction hemorrhage, and perforation. Surgery has been required and deaths have occurred. Such tablets should be used only when indicated and when adequate dietary supplementation is not practical. They should be discontinued immediately if abdominal pain, distention, nausea, vomiting or gastrointestinal bleeding occur. **Precautions:** Exercise caution in hepatic disease, diabetes, surgery, coronary artery disease, epilepsy, E.S.T., and in patients receiving digitalis. **Side Effects:** Electrolyte imbalance, hyponatremia, hypochloremic alkalosis and/or hypokalemia, hyper-

uricemia and gout, bradycardia, drowsiness, skin rashes, hangover, systemic disturbances, weakness, leg cramps, diarrhea, epistaxis, dizziness, urticaria, dry itching skin, nausea, vomiting, palpitation, superficial skin bruises, headache, dehydration, paresthesias, photosensitivity, pancreatitis, jaundice, xanthopsia, thrombocytopenia, leukopenia, agranulocytosis, aplastic anemia, nasal congestion, hypotension, lassitude, loose stools, anorexia, bizarre dreams, peptic ulcer, ulcerative colitis, mental depression. (Ammonium chloride, which may be administered to reverse hypochloremic alkalosis, should not be given to patients with hepatic disease.) **Before prescribing or administering, see package insert.** †Warning: May be habit forming. **Usual Adult Dosage:** Butiserpazide®-25 or Butiserpazide®-50: 1 tablet daily or b.i.d. **References:** 1. Johnson, H. J., Jr.: *Penna. M. J.*: 67:35, 1964. 2. Coodley, E. L.: *Curr. Ther. Res.* 4:460, 1962.

McNEIL

McNEIL LABORATORIES, INC.,
FORT WASHINGTON, PA.

Diagnosis:

cystitis?
pyelonephritis?
pyelitis?
urethritis?
prostatitis?

in any case,
usually gram-negative*

Therapy:

two 500 mg. Caplets® q.i.d.
(initial adult dose)

Indications: Urinary tract infections caused by gram-negative and some gram-positive organisms.

Side effects: Mainly mild, transient gastrointestinal disturbances; in occasional instances, drowsiness, fatigue, pruritus, rash, urticaria, mild eosinophilia, reversible subjective visual disturbances (overbrightness of lights, change in visual color perception, difficulty in focusing, decrease in visual acuity and double vision), and reversible photosensitivity reactions. Marked overdosage, coupled with certain predisposing factors, has produced brief convulsions in a few patients.

Precautions: As with all new drugs, blood and liver function tests are advisable during prolonged treatment. Pending further experience, like most chemotherapeutic agents, this drug should not be given in the first trimester of pregnancy. It must be used cautiously in patients with liver disease or severe impairment of kidney function. Because photosensitivity reactions have occurred in a small number of cases, patients should be cautioned to avoid unnecessary exposure to direct sunlight while receiving NegGram, and if a reaction occurs, therapy should be discontinued. The dosage recommended for adults and children should not arbitrarily be doubled unless under the careful supervision of a physician. Bacterial resistance may develop.

When testing the urine for glucose in patients receiving NegGram, Clinistix® Reagent Strips or Tes-Tape® should be used since other reagents give a false-positive reaction.

Dosage: Adults: Four Gm. daily by mouth (2 Caplets® of 500 mg. four times daily) for one to two weeks. Thereafter, if prolonged treatment is indicated, the dosage may be reduced to two Gm. daily. Children may be given approximately 25 mg. per pound of body weight per day, administered in divided doses. The dosage recommended above for adults and children should not arbitrarily be doubled unless under the careful supervision of a physician. Until further experience is gained, infants under 1 month should not be treated with the drug.

How supplied: Buff-colored, scored Caplets® of 500 mg. for adults, conveniently available in bottles of 56 (sufficient for one full week of therapy) and in bottles of 1000. 250 mg. for children, available in bottles of 56 and 1000.

References: (1) Based on 23 clinical papers, 1512 cases. Bibliography on request. (2) Bush, I. M., Orkin, L. A., and Winter, J. W., in Sylvester, J. C.: Antimicrobial Agents and Chemotherapy—1964, Ann Arbor, American Society for Microbiology, 1965, p. 722.

NegGram
Brand of
nalidixic acid
a specific anti-gram-negative

eradicates most urinary
tract infections...

- Low incidence of untoward effects; no fungal overgrowth, crystalluria, ototoxic or nephrotoxic effects have been observed.

- "Excellent" or "good" response reported in more than 2 out of 3 patients with either chronic or acute gram-negative infections.¹

*As many as 9 out of 10 urinary tract infections are now caused by gram-negative organisms: E. coli, Klebsiella, Aerobacter, Proteus, Paracolon or Pseudomonas?... However, infections of the urethra and prostate caused by non-gonococcal gram-negative organisms are believed to be less prevalent.

Law and Medicine

The "Police Hold"—A Benevolent Abuse

ALMOST DAILY the police bring a person to the psychiatric ward of the county general hospital in Minneapolis or Saint Paul, leaving him in the hands of hospital personnel with "Police Hold" stamped somewhere on the chart or order book. The police do not themselves place the stamp there. Hospital personnel do—in the widely accepted belief that they are executing a valid police power.

Stamping the Record

From the point of view of the police the practice probably stems from so stamping the record of a prisoner in a jail or penitentiary, the prisoner upon expiration of his sentence being then held to answer a further criminal charge. The distinction here is that the hospital is not a place of detention to which the criminally accused has been lawfully committed in the first instance; it is a place to which a prisoner might be sent for evaluation or treatment by a court of competent authority. That is precisely the flaw in the practice of "Police Hold": it is the exercise, by the executive, of a power belonging to the judiciary; the power to commit.

The police have the power to detain a criminally accused person for a reasonable time, until he can be brought before a magistrate for a preliminary hearing.

The place of detention is usually specified by statute as the city jail or the like:

"If . . . arrest be made on Sunday or after sunset or before 9:00 a.m. of any day, then the person . . . arrested should be confined in the City jail, or such other secure place as may be provided or obtained . . . until 9:00 a.m. next following such arrest . . . for hearing . . . "*.

Presumably the County Hospital is a secure place for certain persons. But any detention of the prisoner-now-patient beyond the maximum statutory (and constitutional) period (24 hours) would be a false imprisonment for which participating hospital personnel could be liable.

In Minneapolis the police have become skilled in spotting psychiatric cases. Usually it is psychotic individuals who are brought to the General Hospital for some minor infringement of the law: simple assault or disorderly conduct and occasionally for a felony such as burglary. A "Police Hold" is "put" on the prisoner/patient by rubber stamp. If the charge is sufficiently serious, the police return on a subsequent day to take the accused for further criminal processing, but more often the police never return for the prisoner/patient. He thereupon molts his prisoner status and becomes a patient. Later the supervisory staff agonizes over releasing him without first checking to see whether the police still want him.

*Chapter 630.050 of the Minneapolis Code of Ordinances.

The Saint Paul Ordinances contain no provisions comparable to those of Minneapolis. This is of small significance because it matters little legally where the accused is detained so long as there is no infringement of his constitutional safeguards; these include the right to have counsel present at interrogation*, the right to be warned prior to being questioned**, the right to have counsel present when identified as a suspect†, and other rights.

The Solution

Hospital personnel who actively abet the police in violating any of these rights could conceivably be liable for conspiracy to interfere with civil rights‡ apart from action for false imprisonment or false arrest.

The technically correct procedure is for the police to fetch the prisoner at the hospital and bring him before a magistrate within the statutory time provided; the magistrate then may commit the defendant to the hospital until his next court appearance (or discharge him absolutely if not committing him to jail).

In a sense the police by this practice are using an arrest lawful in its inception to effect a civil commitment, in that they thus compel the mentally-ill individual to become an involuntary psychiatric patient. Generally this has a salutary effect: the patient, often psychotic at the time of his arrest, is prevented from harming himself or others and is brought to treatment; often chemotherapy promptly produces a remission. A humane advantage here to the credit of the police is that a plainly psychotic person is spared a purely formal criminal process which would probably end in dismissal or acquittal, and he is protected and treated medically.

The disadvantages of thus cutting off legal corners should be evident from the foregoing. The safe course for hospital personnel to follow is never to honor a "Police Hold" beyond the statutory time limit for preliminary hearing. Should the prisoner/patient demand his release thereafter, it must be granted him forthwith unless civil commitment has been effected or some principle of law like the doctrine of medical emergency permits detaining him.§

Barlow Smith, LL.B., M.D. #

†*U. S. v. Wade*, U. S., 87 S. Ct. 1926.

‡Under 42 U.S.C.A. §1985.

§Here desperate hospital personnel are prone to seek the bastard ally of the "Police Hold," namely, the "Administrative Hold," a shibboleth by which many a false imprisonment has been sanctioned. This consists of securing the approval of a layman in the hospital administration to detain the patient. Where the responsible physician lacks the right to detain a patient, a lay person cannot confer that right upon him: this too would be an arrogation of the judicial power to commit.

Medicine and Religion

Dying^{*}

SOMEONE HAS said, "Nothing really happens until it happens to you." We read of accidents, losses, suffering, and death, but not until the news item applies to us or our immediate families do we fully understand the emotional shock, the spinning of the mind, and the spiritual strain that comes from a painful, sad experience. "The world looks different to me now," said a young man who had received the verdict of six months to live.

Articles and books have been written and lectures and sermons given on how to face death; yet, when all is said and written, no two people are alike and therefore no fixed procedure can be followed. In all such circumstances the family involved must be considered and also the personalities of the doctors and spiritual advisors. Generally speaking the following can be said:

Spiritual House in Order

Sick or well, a man should keep his house in order. Sudden death can come to a man at any age. A sense of accountability to God and man counsels all of us to see that those who remain after our departure are provided for materially and spiritually—materially, within the range of one's income; spiritually, by living a life of humble obedience to God, usefulness to one's fellowmen and maintaining a disposition that gives a lift to the heart of those who sorrow. The memory of a noble life is, in the long run, the greatest comfort to those who mourn.

To Tell or Not to Tell

The authority to tell a patient he suffers from an incurable disease rests with the family. They will, of course, seek counsel from the doctor and spiritual advisor. If a good rapport has existed before facing the problem of "to tell or not to tell," the decision arrived at will come from love and understanding and will be the right one, to the degree to which we humans can be right.

The acceptance of imminent death, though requiring a painful adjustment, can be and often is fruitful in bringing about a closer bond of affection in the family. This deeper relationship will give to all concerned strength of character and peace of mind which will linger long after death brings separation.

Hope

Hope need never be abandoned! Hope built on wishful thinking or religion as magic will collapse and cast a shadow across the sick and troubled relatives. Hope built on the 23rd Psalm or the 14th chapter of John (which takes in

^{*}Presented at the Annual Meeting of the Minnesota State Medical Association, May 15, 1967.

the whole of life, now and hereafter) puts eternity in the background and places both joy and sorrow in their proper relationship.

Belief in God

When religion has consisted mostly of intellectual assent to a creed, loyalty to an institution, or emotionalism, the facing of death is a severe strain on belief in the goodness of God. Where a man's religion has played a vital part in every department of his life—his home, occupation, friendships and pleasures—he has resources to meet the unexpected as though it were the expected, including death.

Turn to another associated question: "Should life be prolonged by mechanical means when there is no hope of recovery and the patient is in severe pain, unconscious, and reduced to a 'vegetable'?"

It is assumed, if sanction is given to withdraw the mechanical aids to continuation of life, that adequate and acceptable safeguards against careless and hasty diagnoses will be established. Again it must be pointed out that every situation is different: the age of the patient, the circumstances of those paying the bills, the possibility of new information which may be gained if the patient's life is prolonged, and so forth.

However, most ministers are reluctant to give an unqualified 'yes' to withdrawing the means of sustaining life, even in extreme cases. They are fearful that sanction might tend to cheapen life, that many individuals in a coma can be reached, and that they hear what is being said, though they give no outward response.

I personally believe these objections to euthanasia can be met and that letting nature take its course when the body is 'through' is both wise and kind.

Pastor Elmer S. Hjortland
Minneapolis, Minnesota

THERE HAS BEEN much discussion in religious groups as well as in medical organizations as to whether artificial respiration, blood transfusion and the like, should be applied in the case of a patient where there is every indication that death is inevitable. Some religious groups have agreed with this point of view, contending that a "patient has the right to die."

It seems to me that the principle motivating this attitude is the same as that of euthanasia, except in reverse. In euthanasia, death is brought about in a direct way. In the "patient has the right to die" theory, everything is withdrawn that might prolong life.

For instance, when an artificial respirator is keeping the patient alive, I would not accept the responsibility of advising the physician to turn it off, any more than I would counsel him to give the patient a drug that would result in his death.

The moral principle involved is the sanctity of life which we are commanded to preserve and not to destroy, regardless of circumstances.

Rabbi Minda

In Memoriam

'Tis true; 'tis certain; man though dead retains Part of himself; the immortal mind remains.—Homer

AMES W. NASLUND, M.D.

Dr. Ames W. Naslund, 66, Edina radiologist, died August 13. Dr. Naslund, who graduated from the University of Minnesota Medical School, completed his residency in radiology at the University of Iowa. He was a faculty member of the University of Minnesota and former chief of radiology at St. Barnabas Hospital.

Also, he was a member of the Hennepin County Medical Society, American Medical Association, and the Minnesota State Medical Association.

Dr. Naslund is survived by his wife and two daughters.

WILLIAM CYRIL FERGUSON, M.D.

Dr. William C. Ferguson, 57, Walnut Grove physician, died September 5 of a heart attack. He was born in Wagon Mound, New Mexico, and obtained his medical education at the Nebraska University, College of Medicine.

He was a member of the Lyon-Lincoln Medical Society, American Medical Association, and the Minnesota State Medical Association.

He is survived by his wife.

JOHN H. GAMMELL, M.D.

Dr. John H. Gammell, 76, Minneapolis physician, died September 11. Born in Minneapolis and educated at the University of Minnesota, Dr. Gammell was a former chief-consulting oculist at the Minnesota Braille and Sightsaving School in Faribault.

He was a member of the Hennepin County Medical Society and American Medical Association and a Life Member of the Minnesota State Medical Association.

He is survived by his wife and four sons, one of whom is Dr. Gerald Gammell of Oshkosh, Wisconsin.

JAMES A. COSGRIFF, SR., M.D.

Dr. James A. Cosgriff, Sr., 75, president of the Asso-

ciation of American Physicians and Surgeons and Olivia physician, died September 5th at the Renville County Hospital following a long illness. Dr. Cosgriff, who had practiced medicine in Olivia for thirty-eight years, was a past president of the Minnesota Heart Association and the Minnesota Academy of General Practice.

He held many positions of note in his county and state medical societies, namely the Renville, Redwood County Medical Society of which he was president and the Minnesota State Medical Association. He was also a member of the American Medical Association.

He is survived by his wife and seven children, including Dr. J. A. Cosgriff, Jr. of Olivia.

ANDREW D. HOIDALE, M.D.

Dr. Andrew Hoidale, 90-year-old Tracy physician, died July 25. He was born in Tromsø, Norway, educated in Dawson and went to Tracy in 1904 where he practiced medicine until his retirement.

A graduate of the Minnesota School of Medicine, Dr. Hoidale held such city offices as mayor, councilman and health officer of Tracy and also served as a school board member. He was a member of the Lyon-Lincoln Medical Society and the American Medical Association and a Life and 50 Club Member of the Minnesota State Medical Association.

He is survived by one son and a daughter.

JOHN D. KEYES, M.D.

Dr. John D. Keyes, 64, Winona physician, died May 23. Born in Winona, Dr. Keyes received his education in Winona and practiced medicine there until his retirement. He received his degree of doctor of medicine from the University of Minnesota Medical School.

He was a member of the Winona County Medical Society, American Medical Association, and an Associate Member of the Minnesota State Medical Association.

He is survived by two children.

AMA '67 HOUSTON

AMA 21ST CLINICAL CONVENTION • ASTROHALL • HOUSTON, TEXAS • NOVEMBER 26-29, 1967

Plan to attend this year's AMA Clinical Convention in Houston, Texas. Eighteen scientific sessions, four postgraduate courses, breakfast roundtable discussions, color television, and scientific and industrial exhibits will bring you up to date on the latest medical advances. Attend lectures by, and discussions with, our nation's outstanding medical authorities.

Between sessions, enjoy the excellent restaurants, fine shops, visitors' attractions, and mild winter temperatures Houston offers. Mail the enclosed registration and room reservation coupons now, and look forward to an exceptional convention with a holiday plus.

SCIENTIFIC SESSIONS: Cardiovascular Disease; Cardiovascular Surgery; New Cares; Ophthalmology; Geriatrics; Arthritis; Gastroenterology; Cancer; Antibiotics; Endocrinology; General Surgery; Dermatology; Aerospace Medicine; Obstetrics and Gynecology; Psychiatry; Pediatrics; Genitourinary Diseases; and Otolaryngology.

POSTGRADUATE COURSES: Fluid and Electrolyte Balance; Oncology; Cardiovascular Disease; and Obstetrics and Gynecology. Register for these Courses on arrival in Houston at the PG Course Registration booth adjacent to the General Registration area. There is no charge for the Courses, but registration is limited to 200 per Course. The Courses begin promptly at 9 A.M. and 2 P.M. No one will be seated after the Course begins.

BREAKFAST ROUNDTABLE CONFERENCES: Management of Cerebrovascular Insufficiency; Indications and Limitations of Uses of Antibiotics; The Moral and Ethical Aspects of Caring for the Dying Patient; Adolescence, Age of Rebellion, Related Psychiatric Aspects.

**COLOR TELEVISION • MEDICAL MOTION PICTURES
• SCIENTIFIC AND INDUSTRIAL EXHIBITS**

The complete scientific program, plus forms for advance registration and hotel accommodations, will be featured in JAMA, October 23.

Meetings and Announcements

Next to knowing when to seize an opportunity, the next important thing in life is to know when to forgo an advantage.—Disraeli

NOVEMBER

Minnesota Academy of Ophthalmology and Otolaryngology, No date set as yet.

Clinical Reviews

A program of lectures and discussions on problems of general interest in medicine and surgery. Mayo Clinic and Mayo Foundation, Rochester.

Identical sessions are offered on November 6, 7 and 8 and November 13, 14 and 15, 1967, Theater—Mayo Clinic Auditorium, Rochester, Minnesota.

This program is acceptable for credit by the American Academy of General Practice and the College of General Practice of Canada.

The registration fee for this program is \$10.

Those wishing to attend should communicate with Mr. M. G. Brataas, Mayo Clinic, Rochester, indicating which session they would prefer to attend.

Physician's Diary

The general principles of urbanity, politeness, or civility, have been the same in all nations; but the mode in which they are dressed is continually varying. The general idea of showing respect is by making yourself less; but the manner, whether by bowing the body, kneeling, prostration, pulling off the upper part of our dress, or taking away the lower, is a matter of custom.—Sir J. Reynolds

New Location:

Dr. Charles F. Turbak is now associated with Doctors Patrick Meekin, Thomas Meany and Joseph Stenzel in Columbia Heights. . . . Dr. Roger Slanga has opened offices for the practice of medicine in association with Dr. William A. Autrey in St. Cloud. . . . Dr. Milton Sadd has opened up offices in Willmar where he will specialize in dermatology. . . . Dr. Barlow Smith has opened offices for the practice of psychiatry in the Southdale Medical Building in Edina. . . . Dr. Lawrence R. Boies has accepted a position as President of the Deafness Research Foundation in New York City.

* * *

* * *

Dr. Dale J. Eichelberger, Willmar, has been elected to active membership in the American Academy of General Practice.

* * *

Dr. Henry Buchwald, assistant professor of surgery at the University of Minnesota, has been awarded the Samuel D. Gross Prize in Surgery by the Philadelphia Academy of Surgery.

Dr. Buchwald will go to Philadelphia this fall to receive his \$1,500 prize money and present his award-winning thesis: "A Laboratory and Clinical Study of Cholesterol Metabolism and Atherosclerosis as Influenced by Partial Small Intestinal Exclusion."

He is the third University of Minnesota surgeon to receive the Gross Prize for Surgery. Dr. Owen Wangenstein received it in 1935 and Dr. George Moore in 1950. The prize was first awarded in 1895 and has been presented to some 15 surgeons who have made original contributions in their fields.

FIGHTING CANCER WITH FILMS...

...is not news. What's news is that we've embarked on the most ambitious film program *for professional medical audiences* ever launched against a single disease. A half-million dollar film project is underway—with technical advice from the nation's leading medical authorities.

Five of these films are available now—

CANCER IN CHILDREN, DIAGNOSIS AND MANAGEMENT OF CANCER OF THE COLON AND RECTUM, ORAL CANCER, NURSING MANAGEMENT OF THE PATIENT WITH CANCER, and THE DENTIST AND CANCER. The balance will be released in 1967-1968.

As pioneers in the usage of medical films, we know their value as teaching tools. Our Units across the country know, too. Films are a vital part of their professional educational programs. We hope you will contact *your* local ACS Unit about this outstanding new series.

AMERICAN CANCER SOCIETY 

Minnesota Medicine at a Glance

Aortic Stenosis and Unexplained Gastrointestinal Bleeding—
Nordstrom and Myhre

Page 1623

The authors describe a very interesting patient with aortic stenosis who has had multiple hospital admissions for gastrointestinal bleeding, the site and cause of which could not be established. They point out that there have been a number of reports in the literature indicating an apparent association between aortic stenosis and recurrent gastrointestinal bleeding of unknown etiology. The incidence of aortic stenosis in patients with unexplained gastrointestinal bleeding has been reported to be five times greater than in the rest of the population.

The Lifegame—Buckley

Page 1631

The events of life are many and various. Yet they tend to trigger some rather consistent physiologic responses, which are an important part of the "personal life style" of each individual. This paper explores some of the neurophysiologic "groundrules" for experiencing life, and then acting with it, and on it, and in it.

Traumatic Brain Syndrome Undergoing Remission—Luckey

Page 1637

Any disease or illness may be accompanied by psychological and social problems which excessively complicate or even supersede in complexity a patient's organic illness. Physicians must be prepared to foresee and manage all aspects of a patient's illness with the ultimate goal of returning that patient to society as a productive member.

This presentation aptly describes a case of traumatic encephalopathy in which eventual improvement of the patient's organic illness was accompanied by personal and social difficulties that complicated his road to recovery. Several suggestions are made by the author for dealing with these problems.

What's New!

The treatment of psychotic patients with a new drug, Prolixin Enanthate, is graphically demonstrated in a 16-mm. color sound, 39-minute film. This new drug is a unique long-acting tranquilizer given by injection. Film available through Squibb regional offices.

Norlestrin will now be available in a one-milligram tablet, having been cleared by the FDA in mid-June. (Parke-Davis & Company).

Dilantin® (diphenylhydantoin)

PARKE-DAVIS

In untold thousands of epileptic patients... Dilantin has been, and continues to be, the bedrock of therapy.

DILANTIN is useful in the treatment of grand mal epilepsy and certain other convulsive states. Its use will prevent or greatly reduce the incidence and severity of convulsive seizures in a substantial percentage of epileptic patients, without the hypnotic and narcotizing effects of many anti-convulsant drugs.

PRECAUTIONS: Periodic examination of the blood is advisable. Nystagmus in combination with diplopia and ataxia indicates dosage should be reduced. The possibility of toxic effects during pregnancy has not been explored. **ADVERSE REACTIONS:** Allergic phenomena such as polyarthropathy, fever, skin eruptions, and acute generalized morbilliform eruptions with or without fever. Rarely, dermatitis goes on to exfoliation with hepatitis, and further dosage is contraindicated. Gingival hypertrophy, hirsutism, and excessive motor activity are occasionally encountered. During initial treatment, side effects may include gastric distress, nausea, weight loss, nervousness, sleeplessness, feeling of unsteadiness. Macrocytosis, megaloblastic anemia, leukopenia, granulocytopenia, thrombocytopenia, pancytopenia, agranulocytosis, and aplastic anemia have been reported. Nystagmus, lymphadenopathy, lupus erythematosus, erythema multiforme (Stevens-Johnson syndrome), and a syndrome resembling infectious mononucleosis with jaundice have occurred. DILANTIN is supplied in several forms including Kapseals® containing 0.1 Gm. and 0.03 Gm. diphenylhydantoin sodium.

Parke, Davis & Company, Detroit, Michigan 48232

The color combinations of the banded capsules are Parke-Davis trademarks. The orange-banded white capsule identifies Parke-Davis 0.1 Gm. diphenylhydantoin sodium; the pink-banded white capsule 0.03 Gm. diphenylhydantoin sodium.

Lutrexin[®]

HW&D BRAND OF LUTUTRIN

3000 UNIT TABLETS

**IN THE TREATMENT OF FUNCTIONAL DYSMENORRHEA AND SELECTED CASES OF
PREMATURE LABOR AND 2ND AND 3RD TRIMESTER THREATENED ABORTION**

■ LUTREXIN, the non-steroid "uterine relaxing factor" has been found to be useful by many clinicians in controlling abnormal uterine activity.

■ Literature on indications and dosage available on request.

■ No side effects have been reported, even when massive doses (25 tablets per day) were administered.

■ Supplied in bottles of twenty-five 3,000 unit tablets.

(In vivo measurement of Lutrexin on contracting
uterine muscle of the guinea pig.)

HYNSON, WESTCOTT & DUNNING, INC.

BALTIMORE, MARYLAND 21201

(LTR23)

Picture of bursitis

**Parafon Forte helps to relieve pain,
restore mobility . . . stop pain-spasm feedback**

Here is why. PARAFON FORTE provides:

a nonsalicylate analgesic equal to aspirin for the relief of pain,^{1,2} yet unlikely to produce the irritation to the gastric mucosa so often associated with salicylate therapy³

and a skeletal muscle relaxant shown to have up to a 6-hour span of action,⁴⁻⁶ and to retain effectiveness even on continued administration,⁵⁻⁷ but which does not have the central effects of tranquilizing compounds.

Prescribe PARAFON FORTE for lasting spasmolysis and analgesia in sprains, strains, myalgias, low back pain, bursitis and other musculoskeletal disorders. Your patients will appreciate the restored comfort and lasting freedom of movement it usually provides.

treated with Parafon Forte® TABLETS

Paraflex® (chlorzoxazone)* 250 mg.
Tylenol® (acetaminophen) 300 mg.

Cautions and side effects: Use with caution in patients with known drug sensitivity. If a hypersensitivity reaction or symptoms suggestive of liver dysfunction are observed, the drug should be stopped. Occasionally, drowsiness, dizziness, light-headedness, malaise, overstimulation or gastrointestinal disturbances may be noted; rarely gastrointestinal bleeding, allergic skin rashes, petechiae, ecchymoses, angioneurotic edema or anaphylactic reactions may have been drug associated. While *Paraflex* (chlorzoxazone) has been suspected as being the cause of hepatic toxicity in approximately eighteen patients, it was not possible to state that the dysfunction was or was not drug induced. **Dosage:** Two tablets q.i.d. **Supplied:** Scored, light green tablets, imprinted "McNEIL"—bottles of 100.

GENERAL INFORMATION

Authors

Send manuscripts for consideration to MINNESOTA MEDICINE, 375 Jackson Street, St. Paul, Minnesota 55101.

Bibliographic references should conform to the method used by Index Medicus. A maximum of 12 references will be published, but all references will appear in the reprints.

Illustrations, photographs, tables, graphs, and pen and ink drawings are encouraged. If the drawings are not acceptable they will be commercially reproduced and the author will be billed.

All manuscripts will be edited and stylized to conform to the format used in MINNESOTA MEDICINE. The content of the manuscript will not be altered.

Minnesota Medicine Award

An award will be given at the annual meeting to the author of the most meritorious manuscript for the preceding year.

Readers and Reviewers

Diagnosis:

cystitis?
pyelonephritis?
pyelitis?
urethritis?
prostatitis?
in any case,
usually gram-negative*

Therapy:

two 500 mg. Caplets® q.i.d.
(initial adult dose)

Summary of prescribing information

Indications: Urinary tract infections in which gram-negative bacteria are predominant, particularly *Proteus*, *Escherichia coli*, *Aerobacter*, *Klebsiella*, and certain strains of *Pseudomonas*. Gram-positive bacteria are less sensitive to NegGram but favorable clinical results have been observed.

Warning: Use in Pregnancy. This drug is not recommended in the first trimester of pregnancy. However, it has been used in several patients during the last two trimesters without producing apparent ill effects in either mother or fetus.

Precautions: As with all new drugs, periodic blood and liver function tests are advisable during treatment longer than 1 or 2 weeks. This drug should be used with caution in patients with liver disease, epilepsy, severe cerebral arteriosclerosis, or severe impairment of kidney function. Because photosensitivity reactions have been reported in a small number of cases, patients should be cautioned to avoid unnecessary exposure to direct sunlight while receiving NegGram, and if a photosensitivity reaction occurs, therapy should be discontinued. The dosage recommended for adults and children should not arbitrarily be doubled unless under the careful supervision of a physician. Should bacterial resistance develop or additional nonsensitive strains emerge, other effective antibacterial agents should be added to or substituted for NegGram.

When testing the urine for glucose in patients receiving NegGram, Clinistix® Reagent Strips or Tes-Tape® should be used since other reagents may give a false-positive reaction.

Adverse reactions: Mainly mild nausea, vomiting, and other gastrointestinal disturbances; less frequently, sleepiness, drowsiness, weakness, headache, dizziness and vertigo, and rarely cholestasis, paresthesia, thrombocytopenia, leukopenia, or hemolytic anemia in patients with a deficiency in activity of glucose-6-phosphate dehydrogenase. Itching, pruritus, rash, urticaria, mild eosinophilia, reversible photosensitivity reactions primarily involving exposed surfaces, and reversible subjective visual disturbances (overbrightness of lights, change in visual color perception, difficulty in focusing, decrease in visual acuity and double vision), occurred occasionally. Reversible increased intracranial pressure with bulging anterior fontanel, papilledema, and headache has been observed occasionally in infants and children. Toxic psychosis and brief convulsions (the latter generally in patients with possible predisposing factors, and both usually associated with excessive dosage) have been recorded in rare instances.

Dosage and administration: *Adults*—Four Gm. daily by mouth (2 Caplets® of 500 mg. four times daily) for one to two weeks. Thereafter, if prolonged treatment is indicated, the dosage may be reduced to two Gm. daily (1 Caplet of 500 mg. four times daily). *Children*—According to age and weight: approximately 25 mg. per pound of body weight per day, administered in divided doses.

Note: The dosage recommended above for adults and children should not arbitrarily be doubled unless under the careful supervision of a physician. Until further experience is gained, infants under 1 month should not be treated with the drug.

How supplied:

- For adults—Buff-colored, scored Caplets of 500 mg., conveniently available in bottles of 56 (sufficient for one full week of therapy) and in bottles of 1000.
- For children—Caplets of 250 mg., available in bottles of 56 and 1000.

Before prescribing, please refer to complete prescribing information.

References: (1) Based on 23 clinical papers, 1512 cases. Bibliography on request. (2) Bush, I. M., Orkin, L. A., and Winter, J. W., in Sylvester, J. C.: *Antimicrobial Agents and Chemotherapy—1964*, Ann Arbor, American Society for Microbiology, 1965, p. 722.

NegGram

Brand of

nalidixic acid

a specific anti-gram-negative

eradicates most urinary tract infections...

- Low incidence of untoward effects; no fungal overgrowth, crystalluria, ototoxic or nephrotoxic effects have been observed.
- "Excellent" or "good" response reported in more than 2 out of 3 patients with either chronic or acute gram-negative infections.¹

*As many as 9 out of 10 urinary tract infections are now caused by gram-negative organisms: *E. coli*, *Klebsiella*, *Aerobacter*, *Proteus*, *Paracolon* or *Pseudomonas*?... However, infections of the urethra and prostate caused by non-gonococcal gram-negative organisms are believed to be less prevalent.

President's Letter

FOR MANY REASONS I want to make my last President's Letter one to fit the season. Hence I choose to write on the general topic of "Medicine and Religion." I have never been, nor ever will be, one who wears his religion on his sleeve, as it were. However, I am perfectly willing to stand up and be counted when the occasion arises that this type of action is appropriate. Such is the case now.

I propose to tell you about a very personal experience which is, as I prefer to think, a story to further document evidence that there is some Power greater than any we know of on this earth, which guides our destinies. Obviously the first necessary ingredient is Faith. The skeptic, agnostic, or atheist lacks this particular quality, and such is his privilege. But I feel genuinely sorry for anyone who lacks this thing called Faith, as he is missing something which can, in a time of personal tragedy or loss, provide a greater measure of solace than anything else I know of.

As you may have guessed, these letters are written about three months in advance, and it so happens that I have just sustained the loss of both my 93-year-old mother and my 51-year-old brother within less than eight hours during one memorable night in August, 1967. My brother was one of those unfortunates who was born mentally retarded, a victim of mongolism. For years Mother had hoped and prayed that he could precede her in death, so that her devoted and dedicated service on his behalf would terminate before she died.

It happened exactly that way!!! Warren died at 9:30 P.M. on the night of August 28th,

and Mother followed at 5 A.M. on August 29th. I am sure she was aware that he was going to go soon, as she knew of his critical illness before she herself underwent her own final stroke and pneumonia. But it seems inconceivable to me that these two deaths could have occurred by pure chance as close together as they did and also in the sequence in which they did. As I am no mathematician, I cannot quote the odds against its being a coincidence; but those odds must be fantastically high. Yet it did happen.

Such an occurrence should make even the most skeptical of unbelievers pause and reconsider. *Ipse res loquitur!!!* I must freely admit that my own Faith got a tremendous boost when this happened. My mother's own unflagging Faith had been vindicated and substantiated! Had she known about it, and I'm inclined to think that she did, she would not have been at all surprised. Even to those of us who profess ourselves Christians, it was an astounding event!!

We as physicians are in an extremely advantageous position, if we are willing to take the opportunities which present themselves, to quietly and unostentatiously strengthen the Faith of our patients, their families and friends in their moments of doubt and sorrow. We have all encountered deaths among our patients and have been called upon to comfort their families. Can you conceive of a physician-atheist giving any genuine solace to the bereaved? A statement came out of World War II: "There are no atheists in foxholes!!"

Radical Pancreatoduodenectomy

BERNARD F. L'ESPERANCE, M.D.
Two Harbors, Minnesota

APERUSAL OF the medical literature during the past decade gives credence to the fact that radical pancreatoduodenectomy has under great duress finally achieved its just recognition as a treatment of some merit for cancer in the region of the terminal common bile duct and head of the pancreas. That this recognition has been slow in developing is understandable when one reviews the natural history of the operation.

Prior to 1935, diseases of the pancreas were regarded as exercises in diagnostic acumen and surgically abandoned because of the technical difficulties involved and the grave consequences resulting from surgical assault on this organ. Whipple,¹ in 1935, courageously led the avant-garde in the surgical approach to pancreatic disease. His work was greeted with great enthusiasm and vigor; however, optimism was soon replaced by pessimism induced by the subsequent morbidity and mortality following these operations, and, just as important, because of the low permanent salvage rates which ensued. It is unfortunately true that a significant number of the medical profession today still look on the operation with disdain and pessimism. In the light of recent reports this attitude becomes untenable.

Circumstances being favorable, pancreatoduodenectomy becomes the procedure of choice in cases of cancer in the region of the terminal common bile duct and the head of the pancreas. Pessimism should be tempered by optimism; patients presenting with resectable lesions must be given every opportunity for cure—a cure realized only by surgery. Anything less predetermines the patient's fate; undoubtedly many palliative and routine by-pass procedures have deprived a significant number of patients of the opportunity for cure and/or pain-free palliation.

Pancreatoduodenectomy is a formidable undertaking; perhaps this alone deters some from attempting it. With the availability of major medical centers today, if a resectable

lesion is encountered at the operating table and the surgeon is unequipped to perform the operation, a by-pass procedure may or may not be performed and the patient referred for definitive handling of the problem. In most instances "T" tube decompression of the biliary system can be carried out and the patient transferred.

Encouraging survival rates and decreasing mortality rates are being reported by those experienced in this field. Mongé, Judd, and Gage,² reporting from the Mayo Clinic on a twenty-two-year experience (1941-1962) with radical pancreatoduodenectomy, reviewed 239 cases with an overall mortality rate of 19.2%. The five-year survival rate of those operated prior to January, 1959, and broken down as to site of origin of the disease, totaling 134 cases; and a similar series reported by Warren³ et al. giving statistical information on 211 cases of periampullary carcinoma in which pancreatoduodenectomy had been performed with a mortality rate of 11.4% are compared in Table 1. Concerning the carcinoma of the ampulla of Vater Warren stated that when the initial definitive procedure was performed at the Lahey Clinic, 52% of patients survived five years or more. Certainly such reports shed a more favorable light on judiciously applied pancreatoduodenectomy.

Procedure

In each instance the exposure through long upper right paramedian incision has been found to be quite adequate. The procedures were performed under general anesthesia, using nitrous oxide, oxygen, and ether administered through an indwelling endotracheal tube. Appropriate preoperative preparations using whole blood, and parenteral vitamin K, when indicated, were carried out. The procedure we utilized was similar to Waugh's⁴ modification

of the Whipple operation.

Operability is determined by the degree of involvement or lack of involvement of the superior mesenteric vessels, the portal vein, and other regional retroperitoneal structures. This may be determined before committing oneself to the operation by freeing the hepatic flexure of the colon, dividing the right gastocolic omentum, and incising the peritoneum at the inferior margin of the head and neck of the pancreas. The duodenum and head of the pancreas are mobilized by incising the parietal peritoneum lateral to these structures; the right gastric and gastroduodenal arteries are divided. After these primary maneuvers are completed, one is able to pass a finger posterior to the pancreas and duodenum superoinferiorly along the anterior surface of the portal vein and superior mesenteric vessels to emerge at the inferior margin of the pancreas. The decision to initiate or abandon the procedure is made at this juncture. If abandoned, then a biliary by-pass is done; and in some cases, depending on the degree of duodenal obstruction, a gastrojejunostomy is carried out. If regional involvement and liver metastases are present and the lesion is still resectable, consideration can be given to performing a palliative resection. Some authors have gone so far as to resect a portion of the superior mesenteric vessels and portal vein. However, it would seem that the added risk attendant on this, coupled with the questionable immediate or long-range benefit, would hardly justify its performance.

Obesity, which adds to the technical difficulties of all surgical procedures, certainly compounds the problems here. In such cases, it is probably best to forego resection and simply plan on relieving the biliary and intestinal obstruction.

After the specimen, including stomach, head and neck of pancreas, terminal common bile

TABLE I

	Mongé-Judd ²	Warren ³
Total Cases	239	211
Over-all Mortality	19.2	26.9
Site of Origin	Five-Year Survival	Five-Year Survival
Carcinoma of Pancreas	18.2%	6.4% (Head of-)
Carcinoma of Duodenum	38.5	40.
Carcinoma of Common Bile Duct	11.1	36.4 (intrapancreatic-)
Carcinoma Papilla Vater	39.1	31.3

duct, and duodenum, is removed en masse, the jejunum is brought through the defect created when the ligament of Treitz was divided and made to occupy that position formerly held by the duodenum. An essential feature at this point is to ensure adequate blood supply to the replacing jejunum. After the body of the pancreas is adequately mobilized, an end-to-end pancreatojejunostomy is performed, inverting the end of the pancreas into the jejunum, with two rows of interrupted silk and with no attempt at mucosa-to-mucosa apposition. The end-to-side choledochojejunostomy is carried out distally at a comfortable level and an anterior gastrojejunostomy with Hofmeister modification is done. Drainage of the operative area is routine. Postoperatively, nasogastric drainage is maintained until active peristalsis appears and the patient is passing flatus per rectum. Attention to fluid and electrolyte replacement is essential for a successful outcome.

Case Reports

Case 1

A 73-year-old female was seen in November 1959 with a twelve-month history of epigastric and back pain, aggravated by eating and associated with anorexia and a twenty-pound weight loss.

She had undergone a cholecystectomy twenty years previously for cholelithiasis.

Physical Findings

Physical examination revealed an elderly, thin, pale female weighing 130 pounds. The pertinent finding was a questionable tender mass in the right epigastrium. All laboratory studies were negative except for an elevated sedimentation rate of 75 mm. per hour. Intravenous cholangiogram revealed a dilated common bile duct with evidence of an obstructing nonopaque stone in the distal portion.

Surgical Findings

Exploratory laparotomy uncovered a firm orange-sized mass in the region of the head of the pancreas. The common bile duct was dilated two to three times its normal size. Microscopic study of the frozen biopsy section indicated a mucinous adenocarcinoma. The liver was free of metastases; there appeared to be no peritoneal seeding, nor was there any immediate evidence of direct involvement of adjacent vital structures. The lesion appeared resectable and the radical pancreatoduodenectomy was carried out.

During and immediately following the procedure the patient received 1500 cc. of blood.

Postoperative Course

Postoperatively, bile drainage through the drain site was profuse for five or six days but subsided sponta-

neously. Recovery was otherwise uneventful and the patient was discharged on the sixteenth postoperative day. Study of the surgical specimen disclosed a mucinous $7 \times 5\frac{1}{2} \times 5\frac{1}{2}$ -cm. adenocarcinoma of the pancreas, probably originating from the pancreatic duct. There was marked atrophy with almost complete disappearance of the excretory portion of the pancreas but no evidence of regional lymph node metastases, and there was secondary ulceration of the duodenum with tumor tissue protruding into the lumen. The patient has been followed regularly since her surgery. Shortly postoperatively she developed a tendency toward steatorrhea which has been controlled with oral pancreatic extract; and periodic tests for diabetes have failed to show this development. She required re-admission to our hospital in June 1965 because of small bowel obstruction due to a single adhesive band which required surgical division. At this time there was no evidence of intraperitoneal recurrence of the tumor. She is still clinically free of cancer. (This case represents an eight-year survival following pancreatoduodenectomy for a carcinoma of the head of the pancreas.)

Case 2

A 72-year-old male was seen February 17, 1961, with a history of painless jaundice of three weeks' duration. Physical examination revealed a deep icteric tinge to the skin and conjunctiva and an enlarged liver three finger breadths below the costal margin. Laboratory studies were compatible with the obstructive jaundice; liver function tests were normal. X-ray investigations were also normal.

Surgical Findings

Exploration was performed March 3, 1961, after several days of preoperative preparation and revealed a large greenish liver and distended gallbladder. On palpating the pancreas there was a small 2×3 -cm., ill-defined, indurated nodule located in the region of the ampulla of Vater. Choledochostomy was performed and exploration of the common bile duct was negative. A duodenostomy was then carried out and this, too, was without pathological finding. After the head of the pancreas and duodenum were mobilized by incising the peritoneum laterally, numerous biopsies taken in the region of the common bile duct and head of the pancreas were negative. Because of the history, localized nature of the lesion, and lack of obvious distant or local spread, it was decided to perform the Whipple procedure. The cystic duct was long and entered the bile duct close to the proposed site of anastomosis; so a cholecystectomy was also performed. The procedure was carried out as in the previous case. During and immediately following the operation the patient received four units of blood. Postoperatively he developed a pancreatic fistula which closed spontaneously in three weeks.

Postoperative Course

The jaundice and pruritus gradually disappeared, his general condition improved, and he was discharged six weeks postoperatively. Study of the surgical specimen revealed a $3 \times 2 \times 1\frac{1}{2}$ -cm., early mucinous adenocarcinoma of the pancreas (ductal type) with one regional lymph node involved by the tumor. There was also

constriction of the common bile duct by scar tissue and early neoplastic infiltration. He was re-admitted to the hospital in January 1963 with recurrence of his carcinoma and expired January 13. Autopsy confirmed the recurrence, and a stomal ulcer was noted. (This case represents a palliation of approximately 19 months, during which time the patient was relatively free of pain and there was no recurrence of the jaundice.)

Case 3

A 59-year-old female was admitted to the hospital July 20, 1962, with a four-week history of pain and jaundice.

Physical examination revealed severe jaundice with the liver palpable two finger breadths below the costal margin, smooth and nontender. Laboratory studies showed hemoglobin of 10.3 grams or 71%; a white blood count of 8,600; a prothrombin time of 14.5 seconds as compared with control of 12 seconds; a thymol turbidity of 5.2 units; a serum albumin of 3.4 grams; a serum globulin of 2.8 grams; a total protein of 6.2 grams. Pre-operative preparation consisted of blood transfusions to restore the circulating blood volume, administration of parenteral vitamin K, multivitamins, and a high carbohydrate-high protein-low fat diet.

Surgical Findings

Exploration on September 2, 1962, revealed a tremendously dilated common bile duct. The gallbladder had been removed previously. Choledochotomy was carried out and one small stone removed. During the course of dilating the sphincter of Oddi, a small firm mass was palpated in the region of the ampulla of Vater. Transduodenal investigation revealed what appeared to be a carcinoma of the ampulla which was confirmed by biopsy. The Whipple procedure was performed, during which two units of blood were administered. The patient's postoperative course was uneventful and she was discharged home on the twenty-first postoperative day. The pathologist's report on the specimen was adenocarcinoma of the papilla of Vater with one regional lymph node involved.

Postoperative Course

She was seen regularly after surgery and was re-admitted to the hospital in November 1964 with severe back pain and jaundice. Exploration revealed extensive recurrence of carcinoma in the region of the porta hepatis and both lobes of the liver. The patient remained hospitalized and experienced a gradual decline until her demise January 1965. (This patient experienced a two-year palliation.)

Case 4

A 63-year-old female was admitted to the hospital May 14, 1965, to undergo surgery for chronic cholecystitis and cholelithiasis.

Operative Findings

Celiotomy was performed on May 15, 1965, at which time examination of the entire abdomen was negative except for the gallbladder which contained stones and the common bile duct which appeared enlarged. Cholecys-

tectomy was performed. An operating room cholangiogram showed a filling defect in the region of the ampulla of Vater, consistent with a stone. Choledochostomy was undertaken and the duct system scooped and generously irrigated; however, no stones were recovered. The sphincter of Oddi dilated readily and freely admitted a #5 mm. Bakes dilator. A duodenostomy was then carried out and a peculiar sessile type elevation encountered, overlying the papilla of Vater and extending a few mm. on to the duodenal mucosa. Frozen section study revealed a low-grade adenocarcinoma arising from the duodenal mucosa or from the papilla. Radical pancreatoduodenectomy was performed, during which the patient received three units of blood. Convalescence was entirely without incident and she was discharged on the fourteenth postoperative day. Microscopic examination of the resected specimen revealed the presence of a low-grade papillary adenocarcinoma of the papilla of Vater; all lymph nodes were negative.

Since the operation the patient has been followed at regular intervals and has done well with the exception of some difficulty in maintaining her weight.

Case 5

Presently there is in our hospital a 62-year-old male convalescing from surgery performed ten days ago. He presented with obstructive jaundice. Exploration October 31, 1967, revealed a greatly distended gallbladder and common bile duct. A firm ill-defined mass was palpated in the head of the pancreas adjacent to the common duct. Biopsy of an enlarged lymph node in this area was negative. Exploration of the extrahepatic duct system was negative. The pancreas was not biopsied. The decision was made to proceed with pancreatoduodenectomy because of the history and operative findings.

The pathologist reported a well differentiated 2 x 1½ cm. adenocarcinoma of the pancreas pressing on but not invading the common bile duct. All lymph nodes were negative. Tumor was present in nerve trunks and perineural lymphatics.

Comments

The role of radical pancreatoduodenectomy in the treatment of cancer is established. Reasonable morbidity and mortality and acceptable survival rates warrant an increasing judicious application of the procedure for cancer encountered in the region of the terminal common bile duct. Cure can result only if the malignancy is removed, and the only adequate operation that ensures this is the Whipple procedure. What is also not greatly appreciated is the fact that in many instances where cure does not result, reasonable palliation can be effected. The operation is difficult and time-consuming, but this should not be reason to ignore it.

The Role of Biopsy

From our brief experience and the experience of others, it can be reasonably stated that biopsy and frozen section analysis play a somewhat limited role in the differential diagnosis of pancreatic disease. In a large percentage of inoperable carcinomas, microscopic confirmation is possible. However, in the more important instances of operable lesions suitable for pancreatoduodenal resection, definitive diagnosis through biopsy is not always possible or absolutely necessary. Biopsy of the pancreas is by no means an innocuous procedure, especially when one tries to secure an adequate sample for frozen section. There is real risk of severe hemorrhage inherent in biopsy; cases of fulminating pancreatitis have been recorded following attempts to establish diagnosis through this medium. Although a positive diagnosis is reassuring, much time should not be spent in obtaining it. Nothing is more frustrating and unrewarding than spending a great deal of time attempting to establish a diagnosis through biopsy and ending up failing to do so. Biopsy of a regional lymph node may shed some light as to diagnosis when there is metastatic involvement. In some instances clinical judgment alone must determine. If a resectable lesion is discovered and the findings complement the historical data, it is best to proceed with the operation.

Stomal Ulcers

At autopsy Case 2 presented a stomal ulcer, a complication which has been noted by others. In our first two procedures we divided the stomach at the junction of its middle and lower third. However, after noting the development of a stomal ulcer in Case 2, we performed a two-thirds resection of the stomach in Cases 3, 4, and 5 and will continue to resect the greater amount in the future. Some have mentioned that perhaps a vagotomy and a more limited resection would be the preferred method of handling the stomach; however, appreciating the possible effect vagotomy may have on bowel function and the fact that a good percentage of patients following the Whipple procedure do have some bowel difficulties, it would perhaps be best not to perform a vagotomy. In addition, should a fistula develop, the way is open for a possible mediastinitis.

Cholangiogram

Case 4 demonstrates the wisdom of performing cholangiograms at the operating table. Operative cholangiograms have reached the stage where they have become an integral part of biliary tract surgery. Failure to perform these routinely when indications are present denotes a degree of incompleteness in the performance of the procedure. No great amount of special equipment is needed nor is much time expended in performing it. Interpretation of the cholangiograms increases with experience, and ductal pathology otherwise missed will be discovered—a consequence rewarding to both patient and surgeon.

Other Coincident Cases

During the period these procedures were being performed three palliative by-pass operations were carried out, two on patients aged 78 and 73, with inoperable carcinoma of the head of the pancreas and one on a 58-year-old poor-risk, obese, post-stroke patient with carcinoma of the terminal common bile duct. The three survived ten days, two months, and eleven months respectively. A radical pancreatoduodenectomy and a right hemicolectomy were successfully performed on a 75-year-old patient for an adenocarcinoma of the hepatic flexure which had extended to and perforated into the second portion of the duodenum.

Pancreatoduodenectomy is a formidable undertaking and should be undertaken only by those properly qualified. Not only is technical competence essential, but familiarity in the handling of postoperative problems is equally important, particularly in those patients with fluid and electrolyte imbalance. Constant diligent supervision is mandatory and is the sole responsibility of the operating surgeon, aided by round-the-clock special nursing. Our hospital though small is well equipped, possessing a laboratory where all chemical and electrolyte determinations are possible and a well organized blood bank provides ready access for replacement. Competent anesthesia, without which surgery of this magnitude would be impossible, is capably administered by resident physicians with special training in this field.

We have been impressed with the manner in which patients, regardless of their age, have

been able to tolerate a procedure of such magnitude. When proper detail is given to preoperative preparation, anesthesia, surgical technique, and postoperative care, mortality and morbidity can be kept at a reasonable level.

Summary

Five cases of successful radical pancreatoduodenectomy, three for carcinoma of the head of the pancreas, one free of tumor for eight years following initial treatment, one experiencing a nineteen-month palliation, and one experiencing an uncomplicated convales-

cense in hospital at this time; two for carcinoma of the papilla of Vater, one still living without evidence of disease twenty-eight months after surgery, and one succumbing two years after treatment, illustrate the value of this procedure under variable circumstances.

Three instances of palliative by-pass operation, with respective survivals of ten days, two months, and eleven months and a case of radical pancreatoduodenectomy and right hemicolectomy for cancer of the hepatic flexure of the colon were coincidental procedures for similar symptoms.

It's the Law

Attorney Awarded \$500 Fee for Recovering \$45.50 Fee for Physician

Three physicians, who treated the injuries sustained by an employee while at work, submitted fees for \$160, \$60, and \$55.50. The first two claims were rejected because of technical reporting requirements. The third bill received payment of \$45.50. The attorney, who prosecuted the claims of the physicians, requested a fee of \$1225 for his services. In support of his request, he submitted an itemized, sworn statement showing that he had spent about 35 hours in preparing, briefing, and arguing the case. Since the attorney was at least partially successful, he was entitled, under the statute, to a fair and reasonable fee. A fee of \$500 was awarded to the attorney for that part of his work allocable to the portion of the proceedings in which some success was achieved. The court ruled that despite the disproportion between the fee and the amount recovered, the fee was not unfair.

Hayem-Widal Syndrome

Long known as Hayem-Widal syndrome this hematologic disorder is now usually termed "acquired hemolytic anemia." Its clinical characteristics consist of decreased red blood count, spherocytosis, icterus, and splenomegaly. Increased osmotic fragility of red corpuscles to hypotonic salt solution, a positive direct Coombs' test, and the presence of both warm and cold auto-antibodies are valuable supporting diagnostic criteria. Abnormal hemolysins are regarded as the cause. The anemia may be severe and the illness profound. Splenectomy is indicated and usually results in a cure.

Caplan's Syndrome*

DAVID E. DINES, M.D.**

L. EMMERSON WARD, M.D.**

Rochester, Minnesota

IN 1953, CAPLAN¹ called attention to an association of nodular fibrosis of the lungs with rheumatoid arthritis in coal miners. Since Caplan's original description, the syndrome has been reported²⁻⁴ to occur in workers exposed to other types of dust. The clinical complex is of interest because the soft-coal workers' exposure to silica was minimal. It may be not only a syndrome but also an interesting corollary of the interaction between silicosis and hypersensitized tissues. Pulmonary involvement can occur in cases of rheumatoid arthritis without exposure to irritating dust, and it can result in pleural thickening, pleural effusion with a low glucose content, and diffuse or focal interstitial fibrosis. However, the rheumatoid lung characteristically does not show the nodular fibrosis that is seen in Caplan's syndrome.

Observations

Sixteen patients with pneumoconiosis†, consisting of nodular fibrosis of the lungs, associated with rheumatoid arthritis were seen at the Mayo Clinic in the 10 years 1955 through 1964. Twelve were foundry workers; the remainder included a coal miner, a granite polisher, a textile-mill worker, and a rubber-factory worker (this patient had experienced prolonged exposure to rubber dust). Duration of exposure varied from two to 40 years (mean, 18). Ages varied from 31 to 69 years (mean, 55). The pulmonary fibrosis preceded the development of rheumatoid arthritis by one to 14 years (mean, 5.5 years) in six of the 16 patients and occurred after the development of rheumatoid arthritis by 10 months to 15 years (mean, 4.5 years) in 10.

All 16 patients complained of pain and stiffness in the involved joints and of increased fatigability. Fourteen complained of a dry cough and dyspnea on exertion; two had no pulmonary symptoms.

*Read at the meeting of the American Thoracic Society, Pittsburgh, May 21 to 24, 1967.

**Mayo Clinic and Mayo Foundation: Section of Medicine.

†See Test Your Word Score Page 1823.

All 16 had basilar rales on auscultation. One patient had clubbing of the digits; two patients had rheumatoid nodules at the elbow. The rheumatoid process involved hands, wrists, elbows, knees, and ankles. The degree of involvement varied from synovial thickening to destructive changes with rheumatoid deformities. There was no apparent correlation between the severity of the rheumatoid involvement and the severity of the pulmonary involvement.

Five of the 16 patients were tested for lupus erythematosus (LE) cells, and all tests were negative. Sedimentation rate, determined (Westergren) in all cases, varied from 16 to 105 mm. in one hour (mean, 54 mm.). The flocculation test for rheumatoid factor was performed in seven cases and was reactive in five. The serum protein electrophoretic pattern was determined in five cases; three showed increased globulin concentration (mean value, 2.3 gm/100 ml.). Sputum studies in all cases were negative for tuberculosis. Thoracic roentgenograms showed the typical nodular fibrosis in all 16 patients. Pulmonary function was studied in one patient and showed a restrictive and a diffusion abnormality. Lung biopsy (transbronchoscopic) in one patient disclosed interstitial pneumonitis with fibrosis and

Fig. 1—Lung biopsy, showing interstitial pneumonitis with fibrosis. (Hematoxylin and eosin; $\times 75$.)

silica particles present (Figure 1). Open lung biopsy in a second case disclosed interstitial pneumonitis and nodule formation with central necrosis of collagen (Figure 2).

Case Report

A 49-year-old negro male welder was seen in August 1964 because of shortness of breath, dry nonproductive cough, pain with stiffness in the hands, wrists, and elbows, and increased fatigability. He had worked as a welder since 1951. A thoracic roentgenogram was described as abnormal in 1959, but an extensive work-up at that time, including scalene node biopsy, showed no other abnormality.

Average tidal volume, ml.		633	

Physical examination revealed clubbing of fingers, synovitis of both elbows, and leathery rales at both bases posteriorly.

Laboratory data included normal values for blood hemoglobin concentration, leukocyte count, and urinalysis. The rheumatoid flocculation test (Hyland Laboratories) was reactive. A serologic test for syphilis was non-reactive, and the test for lupus erythematosus cells was negative. Sedimentation rate was 75 mm. in one hour (Westergren). A test with purified protein derivative, first strength, was negative, and one with the second strength was positive (2+). The protein electrophoretic pattern showed an increase in concentration of the globulin fraction (2.14 gm/100 ml.). Examinations of specimens of induced sputum, gastric washings, and bronchial secretions revealed no acid-fast bacilli. Hand and wrist roentgenograms were normal. A roentgenogram of the thorax showed a nodular infiltration with a reticular appearance extending throughout both lungs (Figure 3). Review of roentgenograms made elsewhere in 1959, 1961, and 1963 clearly showed a gradual increase in the pulmonary parenchymal infiltration since 1959. Pulmonary function tests (Table) showed a restrictive ventilatory abnormality with decreased carbon monoxide diffusing capacity (found, 9 ml/min/mm. Hg.; normal, 23 to 38).

The patient was instructed in breathing exercises and was advised to follow a regimen of prednisone, potassium iodide, and isoniazid.

Discussion

When Caplan described the association of nodular fibrosis of the lungs with rheumatoid arthritis in coal miners, he reported that 90% of 51 coal miners with rheumatoid arthritis showed more infiltration in the thorax than could be explained on the basis of pneumoconiosis alone. Progressive massive fibrosis also occurs in carbon-electrode workers,² boiler scalers,³ and workers exposed to the dust of iron, brass, sandblasting, and asbestos.⁴ The pulmonary lesions may not be associated with constitutional symptoms, and respiratory difficulty may be slight.⁵ There appears to be no relationship between the severity of the arthritis and the extent of the roentgenographic changes in the thorax.⁶ In most cases the onset of arthritis coincides with the development of the progressive fibrosis; in some cases, however, the characteristic roentgenographic appearance precedes the arthritis by several years.⁷

Gough and associates⁸ showed histologically that the essential difference between the orthodox pneumoconiotic nodules and the Caplan nodules was the presence of an inflammatory

reaction of the rheumatoid type in the latter. The characteristic lesion, consisting of fibrosing pneumonitis with necrobiotic* foci, bears a close resemblance to the subcutaneous nodules of rheumatoid arthritis. The central area of necrotic collagen is surrounded by an inflammatory cellular layer and a zone of fibroblasts containing multinucleated giant cells. The necessary factor for the production of these lesions seems to be the presence of collagen necrosis resulting from the reaction of sensitized lung to dust particles or to dust particles and tuberculosis. One theory has postulated that the fibrotic masses represent tubercular

Fig. 2—Fibrotic nodule. Central area of necrotic collagen is surrounded by inflammatory cellular layer and zone of fibroblasts containing multinucleated giant cells. (Hematoxylin and eosin; x23.)

Fig. 3—Note reticular appearance throughout both lung fields, with nodular fibrosis bilaterally.

*See Test Your Word Score Page 1823.

lesions which have been modified by the presence of coal dust. There is little to support this contention because *Mycobacterium tuberculosis* cannot be demonstrated in the zones of active inflammation. The necrosis of collagen tissue is the fundamental change.⁸

The opacities in Caplan's syndrome are peripherally located, tend to be multiple, and usually affect both lungs. The lesions are similar in appearance to metastatic lesions. They appear rapidly but, once developed, remain unchanged for years. Many will show a mixed picture of round opacities, progressive massive fibrosis, and opacities indistinguishable from those of tuberculosis. Coal miners with rheumatoid arthritis react in a peculiar fashion to any collagen altered by the pneumoconiotic process. Possibly, the rheumatoid patient reacts to inhaled dust particles by means of an unusual hypersensitivity reaction which produces this characteristic picture. There is the possibility that these nodules are rheumatoid in origin and are exactly similar to the rheumatoid nodules commonly seen on the elbows in patients with active rheumatoid arthritis. It has been postulated that rheumatoid nodules develop because of trauma on the extensor surfaces and that they develop in the lung parenchyma because of antecedent damage from the dust particles. A patient with nodular rheumatoid lung disease, but nonpneumoconiotic, with extensive subcutaneous nodules and a positive LE cell test has been described.⁹

Treatment depends on the amount of disability from the pulmonary and from the joint manifestations. The treatment should be the same as for each condition when it exists alone. Irreversible pulmonary hypertension may be

delayed by appropriate treatment with steroids, which decreases the nodular fibrosis. One important aspect of treatment is the use of broad-spectrum antibiotics (tetracycline or ampicillin) with each infection of the upper respiratory tract to prevent a superimposed pneumonitis. Physical therapy, increased rest, salicylates, application of orthopedic measures when indicated, and attention to general health constitute the main treatment of the rheumatoid arthritis. Stronger antirheumatic medications can be used in selected cases.

In each suspected case of Caplan's syndrome, sputum and gastric washings should be studied to exclude active tuberculosis superimposed on a pneumoconiotic process. If steroids are used in the treatment, isoniazid should be administered prophylactically in a dosage of 300 mg. daily after breakfast if the tuberculin skin test is positive.

Summary

Sixteen patients with rheumatoid arthritis and nodular fibrosis of the lungs, seen at the Mayo Clinic in the 10-year period, 1955 through 1964, appeared to have the clinical syndrome, described in 1953 by Caplan, of rheumatoid arthritis with pneumoconiosis in coal miners. Awareness of the entity may prevent unnecessary studies for malignancy, including thoracotomy. The cause is unknown but it may be a hypersensitization reaction to irritating dust particles in the lung in rheumatoid patients, who already have an existing hyperimmune state. Caplan's syndrome may be not only a syndrome but an interesting corollary of the interaction between silicosis and hypersensitized tissues.

Liver

A man's liver is his carburetor—Anon

Complete Heart Block*

An Experimental Study

DONALD W. HANNON, M.D.**
COLEMAN J. CONNOLLY, M.D.**
JESSE E. EDWARDS, M.D.**
St. Paul, Minnesota

HEART BLOCK WAS first treated clinically by Weirich and others in 1957^{1,2} with an external pacemaker for temporary control of surgically induced heart block. Hunter and associates, in 1959, reported the use of a bipolar electrode.³ Chardack et al., in 1960, reported on the use of an entirely internal pacemaker with small cadmium-mercury batteries as a power source.⁴ Since that time over 5,000 units have been implanted. Beginning in 1962 with Dr. Edwards' help we began producing complete heart block under inflow occlusion.⁵ Stimulated by our interest in the conduction system⁵ we questioned whether it might be advantageous to attach at least one of the electrodes to the conduction bundle. This was done and gave an average 20% improvement in cardiac output in heart block over the usual attachment of both electrodes to the ventricular wall.⁷ In a study conducted to determine if this improvement was permanent we found that the intravenous pacer gave about 80% over-all improvement; but we had occasional difficulty with the intravenous pacer causing sudden ventricular fibrillation in the process of placement. In addition, after placement it tended to get out of control easily through simple changes of position or sometimes spontaneously. After surgically placing the intravenous pacer catheter tip in the right ventricular apex and fastening it with a suture, we observed 100% improvement over the usual external ventricular placement (Table 1).

Materials and Methods

In four dogs weighing 30 to 40 pounds the technique of cutting and then cauterizing the

Pacemakers courtesy of Medtronic.

This investigation was supported in part by Public Health Service Research Grant 5 RO 1 H.E.-05694 from the National Heart Institute and in part by a Grant-in-aid from the Minnesota Heart Association.

conduction bundle in the right atrium under conditions of inflow occlusion⁵ caused complete heart block. After a month and with an intravenous pacer in place surgical anesthesia was induced with a 2½ percent solution of sodium pentothal injected intravenously. Assisted respiration was maintained with a mechanical respirator. In three animals the left fifth interspace was opened. In two, attachment of the pacemaker was to the ventricle and the conduction system. In one animal the usual ventricular attachment was used. In the fourth animal through a midline sternal splitting incision, an intravenous pacer catheter tip was placed in the apex of the right ventricle thru a small stab wound. Bleeding was easily controlled with a purse string suture which was also used to maintain the catheter in place. The attached pacemaker was imbedded in the muscle of the upper abdominal wall in all four animals. Cardiac outputs were determined using cardio-green dye and a densiometer^{6,7,8} at intervals of one to two months.

Values for cardiac output were converted to cardiac indices (cardiac output in liters/min./M²). For each study two and sometimes three determinations were done and averaged. Reproducibility of the determinations was within five percent. A total of 60 studies for cardiac output were done.

TABLE I

	Cardiac Output (L/min.)	Cardiac Index (L/min./M ²)	Percent Improvement
With Pacing two Ventricular Electrodes	2.8	2.1	
With Pacing one Conduction Bundle and one Ventricular Electrode	3.0	2.4	14%
Intravenous Pacer	4.3	3.8	80%
Apex Pacer	4.4	4.2	100%

Results

There was a persistent small improvement .3L (14%) with pacing using one electrode attached to the conduction bundle and one ven-

tricular electrode as compared to two ventricular electrodes (Table 1). The intravenous pacer when successful was much improved over both. The cardiac outputs converted to cardiac index for animals with the surgically implanted apical catheter electrode were about twice as good as for animals with epicardial electrode application and 20% better than the intravenous catheter (Table 1).

Comment

The experiments described indicate that implantation of the tip of an intravenous pacer into the apex of the right ventricular cavity gives the best cardiac output in complete heart block. It is probably reasonable to expect an improved contraction of the heart when the conduction bundle is stimulated by one electrode. Just why endocardial stimulation is so superior is not as clear. Perhaps it allows more rapid access to the conduction fibers just under the endocardium.

Summary

In four dogs with recently induced complete heart block three methods of pacing were compared with respect to index of cardiac output. In one dog the two electrodes were implanted in the ventricular wall. In two dogs one electrode was implanted in the left ventricular wall while the other was implanted in the conduction tissue distal to the level of the section which had been made for induction of complete heart block.

In one dog the tip of an intravenous pacing catheter was implanted in the apex of the right ventricular cavity and maintained in place by sutures in the myocardium. In all four dogs an intravenous pacing catheter was passed before surgery and studies done with this in place. The surgically implanted intravenous catheter in apex of the right ventricle gave the best results, averaging 100% better than when the electrodes were placed in the ventricular wall and 20% better than when the intravenous catheter was used.

Diverticulitis Complicating the Diagnosis of a Gynecological Malignancy

FRANKLIN D. LOFFER, M.D.*
El Paso, Texas

JAMES R. BERGQUIST, M.D.
Minneapolis, Minnesota

SURGICAL CONDITIONS involving the female pelvis are not limited to lesions of the organs of reproduction. Acute appendicitis as a cause of right-sided pelvic pathology is well recognized. The differential diagnosis of lesions involving the left side of the pelvis should include diverticulitis of the sigmoid with or without abscess formation. In reviewing the English literature only one article³ points out this diagnostic problem.

Case Report

A 52-year-old-white female was hospitalized because of severe abdominal pain of two days' duration and vague abdominal discomfort and questionable bowel habit changes for the preceeding year. However, a complete physical examination including a pelvic examination and a barium enema nine months before had been normal. Prior to admission her diabetes mellitus had been successfully controlled for the preceding four years by oral antihyperglycemic medication which had followed an episode of acute pancreatitis. She had had some irregular vaginal bleeding following her menopause six years previously and there had also been a persistent serosanguinous vaginal discharge for the preceding one year.

At the time of admission due to abdominal pain her oral temperature was 102.4°F. Her hemoglobin, serum amylase, electrolytes and blood urea nitrogen were normal. The white blood cell count was 14,100 with 82% neutrophils. The blood sugar was 270 mgm %. Her urine was of high specific gravity with 4+ sugar and strongly-positive acetone.

Physical Findings

Her abdomen was flat with active bowel sounds. No masses or organs were palpable, but there was bilateral lower quadrant tenderness. The pelvic examination revealed a clear yellow fluid in the posterior vaginal vault, apparently originating from a red, friable, slightly necrotic cervical lesion which hid the external os. On bimanual examination diffuse pelvic tenderness was elicited. The uterus was enlarged, posterior in position and acutely tender. Microscopic examination of the cervical biopsy done on admission disclosed adenocarcinoma presumably of endometrial origin. The true pelvic findings were later clarified with an examination under anesthesia.

For the first six days of her hospitalization she had a

*American Cancer Society Clinical Fellow, 1964-1965.

febrile course in spite of antibiotic therapy. There was also considerable abdominal pain, requiring narcotics. Constipation was a particular problem. On her seventh hospital day she was examined and a uterine curettage was done under anesthesia. The uterus was probed to $7\frac{1}{2}$ cm. and was found to be anterior and to the right. A mass, approximately $5 \times 6 \times 10$ cm. slightly anterior to the uterus and moving freely with it, was palpated in the left adnexal region. On rectovaginal examination this mass filled the left side of the cul-de-sac. The moderate amount of friable tissue obtained from the uterus was adenocarcinoma, presumably of endometrial origin.

An intravenous pyelogram showed no abnormalities. The first barium enema disclosed an obstruction at the level of the junction of the descending and sigmoid colon. A second barium enema showed a fistulous tract leading to a small cavity at the area of the constriction (Figure 1). The distinction between a neoplastic and an inflammatory lesion could not be made. Sigmoidoscopy was normal to 16 cm..

At this juncture in her workup it was known that the patient had an adenocarcinoma in the uterine fundus that extended to the cervix. However, it was not known with certainty whether this represented a primary uterine tumor or a metastatic tumor with the primary in the ovary or the bowel. In either case there had to be an accompanying abscess secondary to invasion of the bowel wall by tumor. Although the possibility of diverticulitis of the sigmoid colon with abscess was considered, it was felt to be unlikely in view of the normal barium enema nine months prior to this illness. It was felt that an operation would offer the best possibility of a cure if this mass was a malignant tumor.

In consultation with the Surgical Service, a laparotomy was done. The surgical specimen included the lower por-

tion of the descending colon and upper portion of the rectum along with a total hysterectomy, bilateral salpingo-oophorectomy and a generous vaginal cuff. The aortic and pelvic nodes were also included in this en-bloc specimen. Upon dissection of the specimen an adenocarcinoma of the lower uterine fundus and a true diverticulum of the descending colon with abscess formation were found. The abscess was seen lying in the connective tissue between the uterus and colon. The patient tolerated the procedure well. Because of a large vaginal cuff, post-operative radiation was not given.

Discussion

It is impossible to estimate the frequency with which diverticulitis presents a diagnostic problem to the gynecologist. Hurwitz and Solomons,³ in their review of five cases of diverticulitis with abscess formation, found three cases with a preoperative diagnosis of twisted ovarian cyst and one case each with a diagnosis of ruptured ectopic pregnancy and of tubo-ovarian abscess. This error must occur with some frequency, because in most articles discussing surgical management of diverticulitis there are cases in which a laparotomy was done because of the mistaken diagnosis of a gynecologic problem. The lack of data regarding the true frequency of this problem can probably be attributed to authors' reluctance to publish their diagnostic errors.

Diverticulum of descending colon showing fistulous tract to abscess formation.

Undoubtedly diverticulitis often passes through a stage which can mimic a gynecological problem. By the fistulas that are formed, it can be seen that the organs of the female pelvis can be involved by diverticulitis when abscesses occur. This is not a common problem, however, and its rarity can be deduced from the following data. As late as 1957 only a third case of uterosigmoidal fistula due to diverticulitis had been described in the literature.⁵ Vaginosigmoidal fistulas, however, are thought to have an approximate incidence in diverticular abscess of 6.7% or less.^{2,6} Vesicosigmoidal fistulas occur four to five times more often in men than in women,⁴ probably because of the interpositioning of the uterus and its appendages between the bladder and sigmoid colon. Vesicosigmoidal fistulas do occur in women, however, with the approximate frequency of 2.0% of those patients with diverti-

cular abscesses.² This suggests that at least a significant number of diverticular abscesses involving the organs of female reproduction pass through a stage which could be suggestive of a primary gynecologic disorder. Once the fistula is present, however, the diagnostic error probably would not be made.

Many of the features of diverticulitis were present in this patient, but the presence of an adenocarcinoma of the endometrium and a normal barium enema study nine months before made the diagnosis of two separate entities seem ill-advised.

Summary

A patient with an adenocarcinoma of the endometrium and a concurrent pelvic abscess due to sigmoid diverticulitis can cause difficulty in differential diagnosis.

Share Your Medical Journals With Colleagues Overseas

The doctors of the United States are being asked to send their medical journals—after they have read them—to colleagues overseas (Asia, Latin America, and Africa) who wish to have access to current medical literature but, either because of currency regulations or actual cost involved, cannot themselves subscribe to medical periodicals. We can supply you with the name, address, and medical specialty of doctors in these areas who would be happy to receive these much wanted journals, (*particularly specialty journals*), which you will mail direct to your overseas colleague.

This is a direct "Doctor-to-Doctor" program which is being sponsored by the American Medical Association with the collaboration of The World Medical Association to help alleviate the lack of current medical publications and to further international good will. Your co-operation in this program will be greatly appreciated and your contact with these colleagues in other countries, we can assure you, will prove very gratifying. If you wish to participate in this program, send your name, address, and titles of journals you will contribute to DOCTOR-TO-DOCTOR PROGRAM, Ada Chree Reid, M.D., Director, c/o The World Medical Association, Inc., 10 Columbus Circle, New York, New York 10019.

Mr. President—Your Health*

Franklin Pierce—1804-1869

Healthwise Franklin Pierce's early life was uneventful until as a young congressman he yielded to social pressure to imbibe too freely. On one alcoholic spree he and his impetuous companions became involved in rough-and-ready fisticuffs with another group of roisterers. For young Pierce summary retribution followed the rash escapade; he was stricken with and thoroughly subdued by a severe attack of pleurisy. After two cupping procedures, removing first 16 ounces of blood and then 12, he improved and recovered; but for the rest of his life the memory of his youthful folly haunted him with remorse.

At the age of 42 Pierce joined the Mexican campaign as a brigadier general and while on the march westward contracted the insidiously prevalent army-camp intestinal infection with fever and diarrhea, an attack which prostrated and detained him for treatment and convalescence at Vera Cruz. When able, he rejoined his comrades in arms in time to participate in a dramatic military engagement: the Battle of Contreras. While advancing swiftly into action across a rough lava bed his horse shied, then tripped and tossed its rider onto jagged rocks, fracturing his pelvis and dislocating one knee. But Pierce scorned to abdicate to his injuries and retire from action. Instead, he contrived to mount another steed, upon whom he charged heroically into the fray, where he remained until late that night before he capitulated to pain and exhaustion. His recovery was slow and complicated by another assault on his weakened constitution by camp fever and dysentery.

During the succeeding civilian era of Pierce's life his health remained reasonably good except for recurring chest colds and chronic bronchitis, which may have been the precipitating cause of his reverting to overindulgence in alcohol, a habit he had never had sufficient moral stamina to overcome completely. But during this lapse from moderation a particularly severe attack of bronchitis galvanized him into a resolution to abstain permanently, a pledge he kept, while at the same time belatedly embracing religion.

During his later years Pierce was afflicted with chronic stomach discomfort and pain and finally dropsy and lethargy, terminating when he was 64 in a final sleep. The precipitating cause of death was never determined. Medical opinion included a number of pathologies: liver cirrhosis, stomach ulcer or tumor with peritonitis, perforated appendix: any one of these alone or in combination contributing to heart failure. No autopsy was held; the press laconically reported that death was due to "chronic inflammation of the stomach attended with dropsical effusion of the abdomen."

Epilepsy in Children*

WILLIAM R. HEILIG, M.D.
St. Paul, Minnesota

ALTHOUGH EPILEPSY has been known in the human race for thousands of years it is only within the last 100 years that definite treatment and diagnostic procedures have improved. Five to six per cent of all children in the United States will have seizures before they are six years old, and most of these will be due to fever.

Principal Aspects of Epilepsy

It is important to rule out the possibility of all the unusual types of seizures. This we must do by dividing seizures into four major groups: grand-mal, the petit-mal and myoclonic types, psychomotor epilepsy, and the jacksonian** seizures (or in many cases a focal seizure, caused by cortical irritation).

The *grand-mal seizure* is generalized, and rather severe, usually accompanied by a cry or specific symptoms preceding the attack in children. Often stomach disturbances and auras of this type are followed by tonic and clonic movements and eventually by recovery and sleep. Usually these are not localized to one side of the body.

The *petit-mal and myoclonic groups* of seizures are relatively common in children. I have lumped these two together purposely because by electroencephalograph they show a close resemblance. The petit-mal or typical three-per-second high-voltage wave spike complex is rather characteristic of the momentary lapse or of the simple astatic or akinetic seizure (the seizure with the lack of movement). However, the myoclonic seizure is included in this group because of its appearance on the encephalogram; but it is, in my opinion, a very different kind of seizure, also responding to medication very differently. I feel that the electroencephalogram is sufficiently distinct in this particular group to help us to differentiate between the more specific forms of therapy, and for that reason I believe that the myoclonic seizure must, in as many cases as pos-

*Presented at the annual meeting of the Minnesota State Medical Association in Duluth, May 16, 1967.

**See Test Your Word Score Page 1823.

sible, be delineated by encephalograph and history of muscle-jerk seizures of a more generalized and less specifically tonic type than the characteristic grand-mal.

The *psychomotor seizures* were originally called "temporal lobe seizures," primarily because they involved, to a large degree, the function of speech, hearing, emotion and those autonomic functions of the internal viscera (nausea, salivation, vomiting, and symptoms involving the internal and visceral nervous system). These are important because basically they are difficult to treat compared to other types of seizures. They usually require *major* medication, and the prognosis is much more likely to depend upon the focus of the disorder and the cause, which may or may not be more ominous than those outlined above.

The *jacksonian or focal seizures* and those of the so-called localized cortical type encompass a variety of local seizures, often involving a very tiny portion of the body (in other cases a larger section) and the typical jacksonian march, beginning with one portion of the body and spreading to the rest of that side. Usually these seizures are unilateral and it is important to delineate them, because their category includes children suffering from birth injuries, brain tumors, angiomas or blood-vessel groups on the surface of the brain, scars, brain abscesses, and subdural hematomas (especially in infants under one year). These, of course, must first of all be considered in any seizure which *begins* in one area or which is localized or restricted to one area of the body.

Definitive Treatment

In the past, diagnosis has often been rather incomplete, and while most of us were taught in medical school that dilantin and phenobarbital were used for major epilepsy and tridione and paradione for petit-mal seizures, this is today an incomplete and insufficient classification for the specific and satisfactory care of the major forms of epilepsy.

The *grand-mal seizure* in its less serious forms may be cared for satisfactorily with Mebroin, dilantin or phenobarbital. I mentioned phenobarbital last because, except for those children who are brain-injured and require a stronger drug, Mebaral has been a

rather satisfactory drug for the standard school child and causes a distinctly smaller degree of drowsiness, irritability, and skin reaction than does phenobarbital.

The *petit-mal group of seizures* can be treated if separated, as mentioned above, into the petit-mal and/or myoclonic groups. The petit-mal group, primarily the "lapse" seizure or that involving a very minimal degree of movement or loss of either tone or body movement, usually is treated much more satisfactorily with the "dione" drugs, barbiturates, or Zarontin.

The myoclonic group is much more likely to respond to Mysoline, dilantin and, in many cases, also Zarontin. These three drugs may be combined for very severe cases of mixed myoclonic seizures. Mysoline and barbiturates should be avoided in combination since many children show a distinctly severe reaction involving sleepiness or evidence of a brain-stem depression when these drugs are used either in combination, or both combined with one of the other major drugs. The myoclonic seizure specifically involves a muscle-jerk component, and while it may be treated in combination with the "dione" or barbiturate drugs used in the more typical petit-mal seizure, more often than not the drugs used in major seizures will also be required. Psychomotor seizures usually require a combination of drugs used in major motor seizures, such as dilantin-Mysoline, dilantin-phenobarbital or dilantin and *both* of the other two drugs. In treating patients with epilepsy one should never forget the excellent results achieved in some patients by the ketogenic or high-fat diet using the ratio of three grams of fat to one gram of carbohydrate. This is a difficult diet to use. It requires careful co-operation between the hospital dietitian and the family and always a close liaison between the family and the physician. Properly used, with or without additional medication, a ketogenic diet has distinct advantages as well as some very pronounced limitations, such as keeping the child *on* it for any length of time. In the last two years a ten-day trial on Diamox has yielded good correlation with subsequent use of ketogenic* diet in small children. In some infants it also has been possible to use Diamox in the treatment of seizures where other drugs have been inadequate or the children

*See Test Your Word Score Page 1823.

have refused to eat the ketogenic diet.

Treatment of Febrile Seizures

Febrile seizures in children deserve closer attention than any other form of childhood epilepsy. This disease usually occurs between the ages of one and three years and generally takes place if the temperature is 103° or higher rectally. In children with brain damage the seizure may occur with a rectal temperature as low as 101°. Approximately two thirds of these children have an abnormal electrocardiogram and one half have a family history of siblings, parents, or close relatives having had febrile seizures in childhood. Usually the seizures are bilateral, but on occasions where there are some organic factors involved there may be a unilateral or focal component. This unilateral component occurring in a seizure with a temperature, however, is very suggestive evidence of brain damage in addition to the febrile seizure pattern.

Between 5 and 20% of these children will develop epilepsy of a non-febrile type at a later date. For this reason, we must consider, as does Dr. Livingston of Johns Hopkins University Medical School, that any seizure, whether

caused by fever or not, is epileptic and, if unchecked, may become more intense as well as more frequent. In the major types of epilepsy probably 50% of non-treated grand-mal seizures will eventually heal spontaneously, and 90% of the so-called petit-mal epileptics will be cured. As we become more aware of the sub-types of petit-mal seizures, the myoclonic type appears the more serious; it is often associated with brain damage and may be involved in a progressive type of deterioration with mental as well as physical aspects. For this reason it is important in *all* children who have seizures that the proper diagnosis and therapy be instituted and continued for four or five years.

Conclusion

Emphasis has been put on the proper differentiation of the sub-groups of the major epileptic categories and the application of proper medication to these types of seizures. It is important to treat the child at the very onset of the disease in order to minimize both the number of seizures and reduce the probability of recurrence at a later date.

Avicenna* on a Baffling Case

When in his flight from Mahmud of Ghazna he came incognito to Jurjan by the Caspian Sea, a relative of the ruler of that province lay sick of a malady which baffled all the local doctors. Avicenna, though his identity was then unknown, was invited to give his opinion, and after examining the patient, requested the collaboration of someone who knew all the districts and towns of the province, and who repeated the names while Avicenna kept his finger on the patient's pulse. At the mention of a certain town he felt a flutter in the pulse. "Now," said he, "I need someone who knows all the houses, streets and quarters of this town." Again when a certain street was mentioned the same phenomenon was repeated, and once again when the names of the inhabitants of a certain household were enumerated. Then Avicenna said, "It is finished. This lad is in love with such-and-such a girl, who lives in such-and-such a house, in such-and-such a street, in such-and-such a quarter of such-and-such a town; and the girl's face is the patient's cure." So the marriage was solemnized at a fortunate hour chosen by Avicenna, and thus the cure was completed.**

Despise no new accident in your body, but ask opinion of it.—Bacon

Wherever a doctor cannot do good, he must be kept from doing harm.

—Hippocrates

John Hunter's Menagerie

Before going off to war, John made plans to start a menagerie for the study of all kinds of animals. He had leased two acres in Earl's Court in the village of Kensington where he proposed to build a house for his collection.

The design of the house was as unique as the idea of the menagerie was unorthodox. Over the door hung the head of a crocodile with gaping jaws. Four life-size statues of lions, two rearing and two crouching, were set on each side of the building. Back of the house was a den where real lions and leopards were chained. Over the den there was a mound of earth, topped with piles of seashells, in the shape of a little fort on which was mounted a small gun.

The strangest sight was the barnyard. Here all kinds of domestic and wild animals roamed in confusion. Rare birds and serpents, ostriches, geese, and pheasants mingled with buffalo and deer. Fowl with human teeth grafted on the combs, hens with roosters' feathers, goats and dogs were all there for some type of experiment. In a small fishpond Hunter bred eels, leeches, carp, and river mussels. Hedgehogs and other hibernating animals were kept in burrows to yield their secrets of winter sleep. No specimen was too bizarre for the surgeon-scientist to scrutinize. There were goose eggs for the study of embryology, pond water for fresh-water life, the skeleton of a giant dancing bear contracted for with a traveling gypsy when it was alive.

He frequented the pet shops, looking for strange creatures, and begged zoo keepers and members of expeditions for any rare beasts they might encounter. Dead animals were useful, too. Certain parts he pickled in jars, others he dried. The rest were boiled down in a copper vat and the skeletons preserved.*

Autology

E. R. Moras, M.D., founder of Autology, finally arrived in the "booby-hatch." Before that, however, he had achieved a considerable following through advertising in the press, and through exploitation along the lines established by Elbert Hubbard.

Autology is a system of stereotyped hygienic and dietetic advice sandwiched in between a lot of pseudo-science and bad counsel. It is essentially another preachment of Ecclesiastes' urge for moderation in all things. Unfortunately it was carried to the point at which Elbert Hubbard said, "Moderation, equality, work and love—you need no other physician." Moras exploited his book at anywhere from \$10 to \$2, and on the side sold some patent medicines. Finally, his eccentricity went beyond the bounds of legal sufferance. He was arrested for insulting a woman on a train; he attempted to blackmail Leon Mandel out of a million dollars, and appealed to the President of the United States to help him collect \$50,000 from Parke-Davis and Company. So his friends put him in a sanatorium.*

Heredity

A man is the sum of his ancestors; to reform him you must begin with a dead ape and work downward through a million graves.—Ambrose Bierce

Communication between Parents and Child

A Pediatrician's Viewpoint

EDMUND C. BURKE, M.D.*
Rochester, Minnesota

ALTHOUGH PHYSICIANS have long been interested in the emotional relationships between parents and child and the child's adaptation to his environment, recent years have seen more emphasis in this direction. This heightened interest has come about for three reasons: 1, the relative decrease in certain types of childhood diseases, 2, the growing sophistication of mothers and their familiarity with problems of rearing children, and 3, the affluence of the present generation and the Great Society programs, tending to extend the scope and depth of medical care for children.

American mothers have become increasingly concerned with the emotional health of their children, relying on the physician to advise on a host of psychologic issues, from simple matters of child care to problems of behavioral disturbance, weaning, toilet training, and discipline.

Communication

"Communication," derived from a Latin root meaning "sharing," implies a total projection of one's thoughts and feelings, whether by words or action, on the one hand, or on the other, by a deficit of transmission. The more intimate the relationship the better the communication.

Physicians are inclined to regard communication as verbal and forget the equally important, nonverbal signs that communicate as effectively as the spoken word. A glance, a sign, a smile, a wave, a sneer, a smirk, or a grunt, and even stony or impassioned silence convey ideas or feelings. The same words may even be made to have different meanings by the speaker's inflection. In fact, words may not even be necessary. Recently Sorenson and Gajdusek¹ described a type of communication by extraordinary and extravagant eye gestures used among primitive tribes in New Guinea.

*Section of Pediatrics, Mayo Clinic and Mayo Foundation, Rochester, Minnesota.

The goals of communication are *first*, the promotion and establishment of a personal relationship and, *second*, the transmission of information. Communication is a learned or acquired ability, of which speech is the most direct form. Communication has been called the currency of social structure. Dr. M. Robert Wilson, Jr.,* states that without communication man becomes psychotic and withdraws into himself. Communication is to the mind and soul what oxygen is to the tissues. In humans communication has reached the highest level. Electronics has augmented and facilitated communication but has not changed it, in that one man still has to convey his thoughts to another.

The consideration of communication between children and parents is divided according to three age groups: the infant and toddler, the "middle-aged" child, and the adolescent. Each group will be considered in a separate section. A fourth section is about parents.

The Infant and Toddler

At birth the infant suddenly changes his environment from a warm, silent, liquid medium to a world full of sights, smells, tactile sensations and sounds. His potential for responding to his new world consists of the simplest and most primitive of reactions. Perhaps the first significant communication he receives is the comfort and pleasure of being held by his mother. He communicates in turn, becoming completely relaxed in her arms, but anxious, struggling, and vocal in the arms of some other person.

In a matter of days or weeks he learns to communicate his feelings of tension or relaxation. He associates comfort, satisfaction, and relief of tension with his mother. He develops trust in her and a growing sense of his importance to her because she attends to his needs. Failure of an infant to learn trust because of a failure in the development of trust in the mother or a mother figure brings a breakdown in communication and causes him to withdraw into a world of his own. Such an infant is emotionally deprived.

*I am indebted to Dr. Wilson, Consultant in Child Psychiatry, Mayo Clinic, for his suggestions and encouragement in the preparation of this manuscript.

Tension

Some infants are considerably more hyperactive than others. Such an infant displays his tensions by screaming, rooting about, waving his arms and legs, and exhibiting much more than average wakefulness. The "colicky" infant is the infantile personification of tension. He generates considerable anxiety in his parents; on the other hand, sometimes anxiety in the parents generates colic in the infant; thus the whole family is affected. Colic appears to be a physiologic state affecting certain infants for a limited time. It is not caused solely by a nervous or anxious mother but represents an interaction or a two-way communication between mother and infant. A mother may become angry with an infant and may not be able to cope with these feelings unless she discusses them with a physician; or she may become frustrated by the demands he makes on her. Her feelings of anger, unless they are understood and discussed by physician and mother, may be harbingers of future difficulties.

Confidence

As a toddler, the child develops physical skills, greater strength and improved coordination, confidence, and some independence. He asserts this independence in positive ways such as demands for various objects or actions and also in negative ways in the form of resistance. The mother now becomes concerned with discipline, although unaware that she has been applying it in its simplest form from early infancy.

Discipline

The word "discipline" means to teach, and the mother has been teaching the infant through words and nonverbal communication when she has approved or disapproved of his behavior. He may have resisted being put back in the crib or have manifested likes or dislikes for foods; yet his mother has communicated to him that his behavior must be modified. The later disciplines the mother exercises are less subtle, such as the insistence that the child not handle certain breakable objects about the home, that he stay away

from the steps, or that he remain in the yard and not run into the street. It may be necessary to scold him or spank him to emphasize that he must comply with the family rules for acceptable behavior.

Acceptance

The attitudes of his mother, father, and siblings communicate to him acceptance of or dissatisfaction with his activities. Family members do not yield to every whim or tolerate every activity merely because he is an infant; yet their intolerance does not constitute rejection. Communicated to him are loving attitudes and acceptance, whether he has merited praise or disapproval. Anger on the part of either the child or the parents has long since entered into the relationship. The child may display anger because he has been denied something or been compelled to do something. His natural reluctance has to be expected and understood and tolerated to a point. Anger in the parent may be an appropriate reaction if the child is impressed that something will be demanded of him. Parents must realize that anger is a justifiable and appropriate reaction. They must also be aware of the purpose for the anger—that it is a reaction to an action on the part of the child rather than anger toward the child himself. The child has to learn that his anger or a parent's anger is acceptable and need not necessarily hurt, be ugly, or be destructive.

Fear

A child misbehaves as a result of aggressive and hostile impulses, and a too punitive approach by the parent may threaten him so greatly that he withdraws in retaliation never to attempt his actions again. In such circumstances the lesson he learns is one of fear rather than one of correction or education.

Dr. Stella Chess² has risen to the defense of mothers by stating that the response of a child to a parental approach in various areas and at different ages is determined not only by the attitude of the parent but by the child's own temperament. In other words, the mother must not be blamed for problems in the child, since in the complex parent-child reciprocity every action has an equal and opposite reac-

tion. The response of a child to a parent depends just as much on the child's own characteristics of reaction as on the parent's characteristics or on the manner in which the parent applies the communication.

Family Unity

During the toddler and preschool age there are often two main sources of anxiety for parents: eating habits and toilet training. Since the child after infancy enters a phase of reduced growth rate he has a reduced need for food; consequently his appetite is capricious. His parents may regard the amount of food he eats as insufficient for the maintenance of good health and become anxious. This anxiety is often a result of misinformation or folklore and sometimes is a carryover from their own childhood. Since it has been shown that malnutrition is not likely to occur in a child who has no metabolic defect and to whom adequate food is available, supplemental vitamins are seldom necessary beyond early infancy. I would like to regard the family dinner table as a sort of family forum where each one can catch up on the activities of the others during the day. I would cast my vote for preservation of the family dinner hour as essential to interpersonal communication and a sense of family unity.

Toilet Training

Toilet training of the child often depends on the whims of his mother, the amount of experience she has had with previous children, and the amount of resistance offered by the child. It may even be influenced by the mother's own childhood experience. The child often knows what is expected of him but may not be able to accommodate his mother with the hoped for evacuation when he is placed on the potty-chair. Too often she communicates her dissatisfaction, or at times her elation if the child is able to perform.

Little is to be gained in the long run and sometimes a great price may be paid for too early attempts at toilet training. If training is delayed until the child indicates that he prefers to have dry pants and betakes himself to the toilet, the end result will be much more satisfactory. On the other hand, the child who is compliant and performs each time he is set

upon the stool may undergo a change of heart at four, five, or six years of age and begin to retain feces, to wet or soil, or to do both sometimes.

Erikson³ has commented on identification of child with parents. He makes the point that individuals like Hitler and Gorky received little mother love and suffered under a tyrannical father (or grandfather, in Gorky's case). In situations where the child has no satisfactory and warm relationship with either a mother or a father, reactions in the course of personality development can be expected to differ from the norm. A boy who has no satisfactory identification with his father because the father is an inadequate individual, failing to fulfill the role of either father or husband, can hardly be expected to have a satisfactory opinion of his own father and perhaps even of men in general. If his mother fails to fill her role as a normal mother but is either tyrannical or, on the contrary, possessive or smothering, his relationship to women and his estimation of them are affected significantly, sometimes throughout life. Obviously, an environment of love produces individuals capable of love, and one of tyranny is apt to beget tyranny.

The "Middle-Aged" Child

One of the delights of the "middle-aged" child is his growing independence. He is able to dress himself, feed himself, and attend to his own needs. His world is expanding outside the home, and it is normal for him to spend a fair amount of his time away from home. However, this is not ordinarily a source of great concern to the normal parent.

The Anxious Parent

The physician should be concerned about the parent who is anxious or the child who is anxious because of time spent away from home. The basis for anxiety should be discovered and the emotion dispelled. This period of childhood is notable for other behavior, though it may be of only very temporary concern to the parents: specifically, lying, stealing, facial grimacing or tics, and occasional outbursts of independent action. The physician should *caution parents to be aware lest*

they prejudge, convict, and sentence a child before the evidence has been examined and the defense heard. Normally a parent does not immediately conceive of the child as growing up to be a criminal on the basis of a few stolen pennies or some small episode of lying. A child is apt to lose his repentant feelings when he is guilty, if his parents accuse him and then refuse to listen to the facts. Therefore the child, rather than feeling repentant, turns his indignity to anger and resentment.

Home Work

Another difficulty that may arise during this phase in child development is poor scholarship. I have often wondered whether these school problems are not aggravated, perhaps even fostered, by homework. *Educators are fairly well agreed that homework is merely busy work and contributes little toward the education of the child during these early school years.* Parents should take the attitude that schoolwork is given for the child and not the parent and that it is the child's responsibility. He should be left to his own devices and suffer the consequences if he fails to complete his assignments. When poor grades or failures occur, a parent must be careful not to consider the child's failure a parental failure. If the parent takes this as a personal failure, much emotional reaction is generated and often directed toward the teacher. Instances of underachievement in school are usually not due to lack of intellect in the child but rather to lack of motivation, this more often being the result of too much rather than too little parental pressure.

Parental Attitude

The parent must be careful that a reaction toward a child's poor school performance does not communicate to the child the notion that he is inferior and perhaps even willful in the failure. Motivation cannot be demanded; it is more like inspiration and is communicated only through proper parental attitudes, principally patience, understanding, and support rather than through threats, punishment, cajoling, or bribery. Parents often set goals for the child which they themselves failed to attain. Scholarship surely does not flow from homes

where parents have no scholarly values. Too much attention to the sports pages and television and a lack of books in the home are testimony to a parent's attitude regarding intellectual pursuits. Neither can scholarly parents force a scholarly attitude on children. *The child is a great imitator* and, if allowed to direct his own activities with the counsel of understanding parents, he will make the most of his intellectual endowment and be happy in it.

The parent who has had trouble with teachers during his own childhood, perhaps through misbehavior, truancy, or academic failure, may have difficulty preventing these attitudes from being communicated to the child. Often parents sabotage the efforts of teachers by their reaction to what goes on at school. The confusion that this may produce in the child is obvious. Parents may preach about the value of education, yet may sabotage the efforts of the school by berating the teachers or the system. Parents should be aware of a common practice of exploitation of their children for their own gratification. A brilliant performance at a recital or on the athletic field is laudable, but only if it represents initiative and accomplishment on the part of the child without pressure from the parent. Paper routes, lawn mowing, snow shoveling, and other chores are all worthwhile endeavors for the child, provided the job seems to be a good idea to him. A parental decree about jobs for the pre-adolescent is loaded with potentially unpleasant or even dangerous reactions. Parents should be aware that the child's welfare is paramount*; otherwise reasonable resentment toward the parent from the child will be the consequence and the end result unsatisfactory.

"Fostering"

The late Dr. Adelaide Johnson⁴ frequently commented on "fostering" as a factor in misbehavior of children. The inability to set definite limits and to establish definite prohibitions when a child has transgressed is in effect fostering. When a child misbehaves or, on the contrary, fails to do what he has been told to do and parents do not make their disapproval known in definite terms, they are guilty of fail-

ing to establish definite prohibitions. There may be situations in which parents express, in horrified tones, their shock and disapproval of what the child has done, but unless they really feel and express sincerely (communicate) that they do not approve and furthermore that the action will not be tolerated again, they have failed to transmit to the child the right concepts, because they themselves do not have these convictions. In brief, they are phoney as parents if they say one thing and yet lack conviction themselves; they are phoney if they demand one thing and tolerate another in terms of child behavior. Dr. Johnson once recounted an episode in which a child ran away from home and was punished for it; yet the parent obviously obtained a great deal of vicarious gratification from having the child recount in great detail where he had gone, whom he had met, and what he had done. By such a parental reaction, permission was conveyed though prohibition was voiced. *Sometimes parents may foster lying if they try to get a child to lie by asking questions that they know may demand his lying.*

Another common parental injustice is backing a child into a corner from which there is no dignified escape, except by total surrender and indignity.

As the child grows older it becomes obvious that parents, good or bad, increasingly communicate their integrity or lack of it through everything they do or say.

The Adolescent

Adolescence has been termed the age of noncommunication. Actually it is not a phase of noncommunication, but rather a phase of a different type of communication. The adolescent does not often confide in parents as to his thoughts, objectives, and experiences; but if he is observed closely by a considerate and understanding parent, his action and dress will belie his emotional states. *Adolescence is a stormy mountain pass between two tranquil valleys*, childhood and adulthood. The adolescent's world is more turbulent; his behavior traits are reflections of his bodily changes, his sexual awareness, and his questioning of authority. Though the adolescent challenges authority, he needs it and feels anxious and insecure without it. He is often moody, solemn,

*See Test Your Word Score Page 1823.

aggressive, and hostile toward parents and even toward visitors, the latter hostility often intended to embarrass his parents. However, outward signs of inner turbulence need not be considered pathologic. This inner turbulence is reflected in the type of music he enjoys, in sports, in hobbies, and in the "go-go" way he launches himself into activity. For some reason or other, parents who considered themselves adequate while the child was in the earlier phases suddenly seem to be inadequate, and many lose their self-confidence, temporarily if not longer.

The Disillusion of Hypocrisy

Unfortunately, parents often are guilty of a sermonizing monologue: they lecture the adolescent on honesty and good morals; yet they themselves may receive tickets for speeding, may drink to excess, or may behave toward a spouse in any but an exemplary manner. Adolescents are not deceived by hypocrisy but they are disillusioned. Parents should be consoled by the thought that most adolescents have the strength to weather the difficulties of this period. If parents can retain their "cool" and be cautious lest some of their disapproval and reaction provoke adolescents into rash behavior, things will gradually work out.

Antisocial Behavior

Parents should be more concerned if the adolescent shows preoccupation with physical development, anxiety over the sexual role, a paucity of rebellion, excessive shyness, antisocial behavior, sudden or gradual loss of interest in environment, excessive feelings of guilt, and failure in school. Often during these difficult periods the parent needs more guidance than the adolescent. The adolescent is gradually able to work out his emancipation from dependency on parents if the father or mother does not make this more difficult by being too possessive, domineering, or demanding. While the adolescent is being encouraged to mature, to form personal convictions, and to chart an independent course of action, his achievement of these various characteristics often threatens a parent and brings about parental disapproval or denial toward the adolescent.

Characteristically, the adolescent is disorderly in his room. Magazines and clothing are strewn about. Dirty clothes remain under the bed. Radio or record players blare loudly. Even such simple personal habits as brushing the teeth are often neglected, yet on the contrary the hair may be shampooed daily and the cologne may be applied to the point of near asphyxiation for the rest of the family. The adolescent behaves as at least two different persons. He may present one face to his family and yet another to his friends. But are not parents themselves guilty of such complex performances? May not they present one face to the family, another to their colleagues, perhaps another to their subordinates, and still another to their superiors?

The adolescent is apt to set king-sized goals for himself—goals that can hardly be attained by his pint-sized efforts. He may have ambitions to be a great athlete or musician, but he cannot be bothered with the discipline of practice. An adolescent begins to attain his real identity when he no longer pursues goals that he cannot realistically hope to reach.

With the Group

Though parents may think that adolescents are radical because of their dress and general appearance as well as their behavior, adolescents are actually conservative in that they do not want to be regarded as different from their peers. The emotional struggles over masculine and feminine strivings, over aggressivity or passivity, are apparent in boys in the long-pointed high-heeled shoes, the curling hair, the long sideburns, and the toiletries. Most of these adolescents want to remain with the group because they thereby avoid personal responsibility and perpetuate their emotional dependency, not on parents but on the crowd.

Often it is possible to understand adolescents better by studying their dress. Easson⁵ has stated that girls seem to be one or two years ahead of boys in establishing identity. A young man struggling with rebellious and aggressive urges proclaims his feelings in reds and in garish dress, the girls in pinks and yellows. The appearance of overneatness and fussiness in clothing, hair styles, and general appearance may suggest rigid compulsiveness. Anxiety may be represented by disarray and disorgani-

zation of the adolescent's dress. Some parents have noted that adolescents have worn "upset clothes," or "runaway shoes," or a black T-shirt when things are going wrong for them.

Parents are not wise when they go to extremes to keep peace in the family. Often a blowup does an adolescent good. It gives him a chance to get rid of feelings bottled up inside that make him restless and discontented and generally hard to get along with. However, parents should be cautioned to be careful about provoking adolescents into a blowup which may stampede them into taking an unreasonable course of action that will have rash or bitter consequences.

The Parents

Missildine⁶ has stated that emotional problems in the child are a reflection of the pathogenic nature of the attributes of his parents. These emotional problems are intensified when parental attitudes interact to create an atmosphere of conflict in the family. Normally there is an emotional interchange between husband and wife, but when conflicts are deep and prolonged they institute what is referred to as a marital problem.

The parent's view of a child often becomes skewed and distorted because of his own conflicts; then the child becomes a pawn, his allegiance a goal in the marital war, or a weapon to be used by one partner against the other.

The chief difference between children and adults is that children have parents to guide and instruct them and to create the emotional atmosphere in which they all live. Though many persons come from homes where their parents treated them as individuals and with firm and uncritical limits and where a mutual atmosphere of respect prevailed, some are not so fortunate. Their parents did the best they could; but being only human, they had problems that distorted or prevented their regard for and treatment of their children. When such children become adults, they are guilty of these same errors. They tend to recreate in-

side themselves the atmosphere of their childhood homes.

It is apparent that the total quality of each parent is communicated to the child genetically or through living together. One's integrity is on the line. The role of a conscientious and loving parent requires continual self-improvement. If, as an adult, he tends to be distrustful, suspicious, easily tempted to minor infractions such as cheating the grocer or sending the over-aged children to the theater for half price, he can expect the same set of values in his offspring. If husband and wife feel little respect for each other, as reflected in speech or attitude, how can they expect to inculcate a different set of values in their children? Temper tantrums, dish throwing, and cursing are just as immature for adults as for children.

Although adolescents seem to bicker and to harangue one another, they are nonetheless deeply affected by parental disagreement because it rocks the very foundations of their own security. They have parents on a pedestal, and to see a parent fall from a place of respect is a crushing blow not easily overcome. On the other hand, differences of opinion handled in a mature fashion convince the adolescent that some minor problems are a part of normal family life and that resolution may be accomplished without serious consequences.

As physicians we can reassure parents that their role as parents is probably the greatest challenge that life will present. It is one continuous struggle with new adventures; but it is never dull despite frustrations, disappointments, and few triumphs. It is exacting because it demands continual self-improvement and sacrifice. The gratifications come not as great and solemn events but as little experiences and an occasional awareness of a job well done. For the conscientious parent, rearing children is not just a hobby or a spare-time job, but rather a total investment of self. Whereas spoken and printed words may be the commodities of communication for the outside world, the actions of parents are the most eloquent means of communication as far as the family is concerned.

As scarce as truth is, the supply has always been in excess of the demand.
—Josh Billings

It Was a Family Tradition

Father used the spare bedrooms in the house for performing operations such as would be done today only in a hospital, with every conceivable equipment to hand and assisted by trained anesthetists and nurses. He did these as a matter of course, and mother helped him, also as a matter of course.

Naturally I wasn't present when father removed the tumor from Minnie Fenstermacher, but I am certain that in spite of his crude instruments and limited facilities it was done so deftly as to have earned the respect of a modern surgeon—and a little awe, as well, at his success under those conditions.

The patient stayed for a couple of weeks to recuperate, nursed by mother and tended by Abbie. The tumor, a fatty, fleshy growth, considerably larger than a baseball, was put in a tub of water and set on the second floor back porch until father would have an opportunity to put it in alcohol and add it to his collection of similar trophies of the operating table.

Neither he nor mother knew, of course, that their youngest son spent a happy, six-year-old afternoon at a new diversion. I had gotten a long shingle from behind the barn and split it so as to make a nice bat. With this I played a game all afternoon, hitting the tumor back and forth across the tub.

It was natural, therefore, that I should feel destined for medicine. All my play was of doctors and hospitals. My favorite patients were dogs, and by the time I was nine or ten I had established on the second-story back porch a regular hospital for all the stray animals in town.*

Bone Grafts on the Frontier

An operation performed by a Texas doctor, C. W. Truehart, was a striking demonstration of frontier medical skill. A young man had received the full blast of a shotgun in his left shoulder at short range. Cleaning the wound of gun wadding, fragments of clothing, and shot, the doctor applied skin grafts. The wound finally healed except for the clavicular region where a three-inch gap in the bones allowed the shoulder to droop.

Dr. Truehart rounded up a collection of healthy dogs. Nine weeks later he removed the granulation tissue, and between the ends of the youth's bones he inserted small periosteum and bone grafts taken from the dogs, which he chloroformed for the purpose. Eight out of ten grafts took. In two months the incision was healed; the clavicle was the correct length, and the shoulder did not droop.*

Friendship lives on its income, love devours its capital.

—Arsene Houssaye

If you make people think they're thinking, they'll love you; but if you really make them think, they'll hate you.—Don Marquis

Let's be specific about Campbell's Soups... and reducing diets

There are more than 30 million people in America who are overweight. During the next year, you probably will see more than 1,000 of them in your own practice.

One good way to help these patients is to give them a reducing diet based on ordinary eating patterns.

Campbell has prepared a sensible plan for weight control based on ordinary eating patterns. The plan consists of a patient instruction booklet and a set of menus which provide approximately 1,200 calories daily. The menus are balanced to provide the minimum daily requirements of nutrients.

To obtain a supply for your office write to:
Campbell Soup Company, Box 265, Camden, N. J. 08101

For the ambulant patient with hemorrh

♦ ♦ ♦ METAMUCIL®

brand of psyllium hydrophilic mucilloid

Relieves strain

Metamucil produces soft, well-formed stools that minimize pain and strain and reduce the chance of thrombosis in hemorrhoidal veins.

Softens stools

Metamucil, a highly purified vegetable colloid, absorbs water, hydrates the intestinal contents and produces a demulcent "smoothage" that aids healing of hemorrhoids and anal fissures.

Reduces pain

Metamucil reduces pain by eliminating the abrasive irritation of hard, dry stools.

Restores bowel function

Metamucil produces a gentle distention of the intestinal wall that stimulates natural peristalsis and helps reestablish normal, rhythmic bowel function.

And in constipation...

Metamucil furnishes, as it has for more than 30 years, the simple physiologic corrective to constipation, eliminating both hard stools and the need for harsh laxatives.

Usual Adult Dosage:

One rounded teaspoonful of Metamucil powder in a glass of cool liquid, or one packet of Instant Mix Metamucil in a glass of water. An additional glass of liquid is helpful.

Against these three major pathogens...

Pneumococci

Penicillin-Sensitive
Staphylococci

Beta-Hemolytic
Streptococci

V-Cillin K[®] provides dependable oral antibacterial therapy

because it combines a high degree of activity...

V-Cillin K has been shown to be effective in the treatment of streptococcus and pneumococcus infections as well as infections caused by sensitive strains of staphylococci. It may be used for the prophylaxis of streptococcus infections in patients with a history of rheumatic fever and for the prevention of bacterial endocarditis after tonsillectomy in patients with a history of rheumatic fever or congenital heart disease.

with high blood levels, even when taken with food

V-Cillin K is stable in acid and immediately soluble. High serum levels, therefore, are reached rapidly. Because it is acid stable, V-Cillin K is well absorbed even when taken close to mealtime. These desirable properties help make V-Cillin K a dependable penicillin for oral use.

V-Cillin K[®] 701449 **Potassium Phenoxyethyl Penicillin**

Now available: V-Cillin K[®], Pediatric,
for Oral Solution, 250 mg. (400,000 units)
per 5 cc. of solution.

(See next page for prescribing information.)

New 500 mg. tablets...a more convenient way to give high doses

Description: V-Cillin K, the potassium salt of V-Cillin® (phenoxymethyl penicillin, Lilly), combines acid stability with immediate solubility and rapid absorption. Higher, more rapid serum levels are obtained than with equal oral doses of penicillin G.

Indications: Streptococcus, pneumococcus, and gonococcus infections; infections caused by sensitive strains of staphylococci; prophylaxis of streptococcus infections in patients with a history of rheumatic fever; and prevention of bacterial endocarditis after tonsillectomy and tooth extraction in patients with a history of rheumatic fever or congenital heart disease.

Contraindication: Penicillin hypersensitivity.

Warnings: In rare instances, penicillin may cause acute anaphylaxis which may prove fatal unless promptly controlled. This type of reaction appears more frequently in patients with a history of sensitivity reactions to penicillin or with bronchial asthma or other allergies. Resuscitative drugs should be readily available. These include epinephrine and pressor drugs (as well as oxygen for inhalation) for immediate allergic manifestations and antihistamines and corticosteroids for delayed effects.

Precautions: Use cautiously, if at all, in a patient with a strongly positive history of allergy.

In prolonged therapy with penicillin, and particularly with high parenteral dosage schedules, frequent evaluation of the renal and hematopoietic systems is recommended.

In suspected staphylococcus infections, proper laboratory studies (including sensitivity tests) should be performed.

The use of penicillin may be associated with the overgrowth of penicillin-insensitive organisms. In such cases, discontinue administration and take appropriate measures.

Adverse Reactions: Although serious allergic reactions are much less common with oral penicillin than with intramuscular forms, manifestations of penicillin allergy may occur.

Penicillin is a substance of low toxicity, but it possesses a significant index of sensitization. The following hypersensitivity reactions have been reported: skin rashes ranging from maculopapular eruptions to exfoliative dermatitis; urticaria; and reactions resembling serum sickness, including chills, fever, edema, arthralgia, and prostration. Severe and often fatal anaphylaxis has occurred (see Warnings). Hemolytic anemia, leukopenia, thrombocytopenia, and nephropathy are rarely observed side-effects and are usually associated with high parenteral dosage.

Administration and Dosage: Usual dosage range, 125 mg. (200,000 units) three times a day to 500 mg. (800,000 units) every four hours. For infants, 50 mg. per Kg. per day divided into three doses.

See package literature for detailed dosage instructions for prophylaxis of streptococcus infections, surgery, gonorrhea, and severe infections.

How Supplied: Tablets V-Cillin K, U.S.P., 125 mg. (200,000 units), 250 mg. (400,000 units), and 500 mg. (800,000 units).

V-Cillin K, Pediatric, for Oral Solution, 125 mg. (200,000 units) and 250 mg. (400,000 units) per 5 cc. of solution (approximately one teaspoonful). [042567]

Perspectives in Medicine*

IN A RECENT TALK on the problems of metropolitan planning, a strong plea was made by the speaker in support of a metropolitan commission then being laboriously debated in the State Legislature. The speaker stated that if every citizen of the Twin Cities could take a trip over the area in a helicopter, particularly at night, there would be complete unanimity of opinion regarding the pressing need of a potent Metropolitan Commission. One would immediately appreciate the absurdity and artificiality of boundaries between our various communities, municipalities and villages in relation to the whole.

Similarly, in this era of rapidly changing social and scientific concepts, our profession urgently needs means of gaining the broadest possible perspective of medicine, historically, socially, scientifically, and practically, so that we can appreciate and recognize real values and preserve them for the future. Also, we must learn to recognize artifacts, sort them out and find ways to discard them.

For all but a century of the 3000 years for which there is a record of medicine, the physician had little to offer his patient in a

modern, scientific, curative sense. His continued high regard by society was derived from his dedication to duty, compassion, empathy** and devotion to his patient, qualities that you no doubt are still taught informally and by example in our schools but are hardly subjects for inclusion on your examinations. In our generation, when for the first time in history we have much to offer our patients in a curative sense, medicine has toppled from its pinnacle of public acclaim. During the many years when the physician employed his art in caring for his patient, the public forgave him his shortcomings, did not expect perfection of him and allowed him to maintain his independence. Indeed, it was essential that he remain independent when he practiced in a highly individual fashion, as this close interpersonal attachment to his patient was an essential ingredient of the practice of his art. But it was his devotion to his patient, his sincere efforts to help and comfort a sick fellow man that society has always recognized, respected and honored. Certainly in a physical sense there is hardly anything noble about incising an abscess or producing an avenue to drain accumulated, decaying body excreta, other than that they are done to relieve suffering or save the life of another human creature.

*From a talk given to the graduating Senior Class of the University of Minnesota Medical School at the annual Minnesota Alumni and medical student dinner, April 26, 1967.

If hypothyroidism leaves your patient feeling like this...

consider

LETTER[®]

(SODIUM LEVOTHYROXINE,
ARMOUR) TABLETS

Synthetic Thyroid Replacement Therapy

Letter[®] provides all the advantages of the synthetically pure chemical sodium levothyroxine. Dosage is precise and potency is consistently uniform.

and

Letter[®] is micronized to provide maximum opportunity for full absorption and clinical response.

In addition Letter[®] is distinctively color coded with an identifying number stamped on each tablet to provide accurate dosage control.

Indications: Hypothyroid conditions. **Contraindications:** Thyrotoxicosis, acute myocardial infarctions unless associated with hypothyroidism. In hypothyroidism with hypoadrenalism coadministration of corticoids with LETTER[®] is recommended. **Precautions and Side Effects:** Excessive dosage may result in diarrhea, cramps, palpitation, nervousness, rapid pulse, sweating. If symptoms appear, discontinue medication for several days, then reinstitute at a lower level. Since myxedema patients with heart disease may suffer seriously from abrupt increases in dosage, caution should be exercised in adjusting dosage. **Dosage:** Generally, the initial adult dosage is 0.1 mg. daily. This may be increased in small increments every one to three weeks until proper metabolic balance is achieved. **Available:** Bottles of 100 tablets, in six potencies: 0.025 mg. (violet), 0.05 mg. (peach), 0.1 mg. (pink), 0.2 mg. (green), 0.3 mg. (yellow), and 0.5 mg. (white).

ARMOUR PHARMACEUTICAL COMPANY • CHICAGO, ILLINOIS

It is devotion to the service of mankind, be it in medicine, politics or religion, that has always gained the respect and admiration of society. This is a highly personal act, one that you cannot legislate, unionize, socialize or regiment. In our modern era, the addition of science to the art of medicine has brought many unforeseen benefits to mankind. Although the list of diseases that now can be considered curable is far beyond the imagination of the most visionary physician of a generation ago, we will continue to struggle with unsolved problems that are many times greater and more numerous than those that have been brought under control. In a sense, we all are and always will be on a sinking ship. The only variant is time. Such being the case, in spite of our much publicized successes, we have no basis for assuming any pose of perfection. Nevertheless, because of injudicious publicity and notoriety brought about by occasional publicity-conscious members of our profession and news media ever ready to feed the voracious and sensational appetites of a health-conscious public, perfection is what the public has come to expect of us. We have allowed our success to be overpublicized, we have permitted the press to promise cures in

the offing which we cannot produce and we have had created for us an atmosphere and belief that science will conquer all. The facts of the matter are that this type of glamour has tended to erode the art of medicine, and as a result, to depersonalize medicine. As this trend continues, the human qualities of medicine are submerged and lost; it ceases to be an art and becomes a highly skilled craft. Crafts, but not arts, are unionized, standardized and socialized.

If we lose our dedication to the dignity of man in the practice of medicine, we lose also the moral force that gives it substance. When we subtract this quality from medicine, it becomes a branch of zoology with an exaggerated preoccupation and concern for a single animal species. In your busy days ahead, remember to practice your art. Do this not as a set of slick bedside manners to substitute for competence, or as a bag of tricks for considered rational thought, but do it in the sense that you bring sincerity, skill, devotion and kindness to your patient. Walk humbly with your fellow man, for you will have great need to do so.

Minneapolis, Minnesota

Niacin: Another New Cure for Schizophrenia?

THERE ARE TWO current biochemical lines of investigation to the study of schizophrenic illness.³ Abnormalities in plasma proteins, for example, have been postulated, but results so far seem essentially inconclusive and unspecific, and may be related to the effects of chronic institutionalization. Disturbances in amine metabolism have also attracted considerable attention with abnormal derivatives of epinephrine being implicated.⁵ Adrenolutin, for one, certainly produces changes in perception. With this metabolite hypothesis in mind, Hoffer and Osmond¹ have used massive doses of niacin (or its relative nicotinamide) as methyl acceptors, for competitive blockade. Because the toxicity of this vitamin (B-3) is extremely low, their regimen of three or more grams per day has induced few side effects.

Vitamin C and penicillamine (Cuprimine) have supplemented niacin in certain cases in their hands. They report good results, but there has been little confirmation and little enthusiasm for their vitamin therapy in schizophrenia. With nicotinamide being an integral constituent of nicotinamide adenine dinucleotide, also called Coenzyme 1, or DPN, Hoffer and Osmond² turned to employing this substance, advanced striking claims for its quick effectiveness, and suggested that schizophrenia is a nicotinamide adenine dinucleotide-deficiency disease. The first published reports from other research facilities on nicotinamide adenine dinucleotide (by Kline et al.⁴ for example) have produced definitely negative findings. Much research is in progress, but judgment must be suspended about niacin and nicotina-

Before prescribing, see complete prescribing information in SK&F literature or *PDR*. A brief precautionary statement follows.

Contraindications: Glaucoma, prostatic hypertrophy, stenosing peptic ulcer, pyloroduodenal obstruction, or bladder neck obstruction.

Precautions: Use cautiously in the presence of hypertension, hyperthyroidism, coronary artery disease; warn vehicle or machine operators of possible drowsiness.

Usage in Pregnancy: Use cautiously, especially in the first trimester. **Note:** The iodine in isopropamide iodide may alter PBI test results and will suppress ^{131}I uptake; discontinue 'Ornade' one week before these tests.

Adverse Reactions: Drowsiness; excessive dryness of nose, throat or mouth; nervousness; insomnia. Other known possible side effects of the individual ingredients: nausea, vomiting, diarrhea, rash, dizziness, fatigue, tightness of chest, abdominal pain, irritability, tachycardia, headache, difficulty in urination. Thrombocytopenia, leukopenia and convulsions have been reported but no causal relationship has been established.

Adenoidectomy for Secretory Otitis Media

DR. DONALDSON* has presented the indications for tonsillectomy and adenoidectomy in a logical fashion which should be helpful to physicians actively engaged in the care of children.

Secretory otitis media resulting from adenoids obstructing the pharyngeal orifice of the eustachian tube is a common problem and should be dealt with aggressively. There are three good reasons for this statement. First, these ears are often very susceptible to recurrent acute suppurative otitis media and its complications; second, a child in preschool educational activities or in school with a 30 to 40

db bilateral conductive loss of hearing resulting from sterile fluid in the cavities of the middle ear is handicapped; and, third, long-standing secretory otitis media as an etiologic factor in the formation of an epitympanic cholesteatoma (primary acquired cholesteatoma) has been recognized and continually emphasized since 1890.¹

When adenoidectomy is performed for secretory otitis media it must be done under direct vision for thorough removal, with utmost care not to injure the opening of the eustachian tubes and in association with myringotomy, preferably with the aid of a dissecting microscope.

and well-controlled studies are noted and will continue to present problems in comparative data.

Unfortunately, an awareness of the character and complications of drug therapy and the establishment of improved means of administration have not been accompanied by the rapid development of more effective chemotherapeutic agents. For the present, therefore, workers who direct their efforts toward

improving the results of treatment of malignant disease must utilize currently available drugs and techniques. These efforts will involve continued attempts at earlier detection and additional trials with dosage schedules and timing of chemotherapy. The use of an individual drug and combinations of drugs in conjunction with surgical treatment and irradiation will be a necessary part of these efforts.

Richard G. Hahn, M.D.
Rochester, Minnesota

Tendon Injuries*

THE LACERATED finger tendon generally heals without difficulty; for it to glide is another matter. Tendons heal by proliferation of surrounding tissue, either paratenon or sheath. Evidence that there is any intrinsic tenoblastic activity is lacking. Proliferation of fibroblasts in the peritendinous tissue is evident by the fourth post-injury day and is continuous for about three weeks. If by chance or operative intervention the tendon ends are in approximation, bridging and eventually firm anastomosis occurs. Unfortunately, proliferative activity is as unselective as it is exuberant, and adhesions are the rule. Hopefully, in time these adhesions will stretch and permit useful motion. Obtaining a gliding tendon anastomosis depends on many factors: location of tendon laceration, degree of initial trauma, type of treatment (anastomosis or tendon graft), timing of the definitive procedure, mechanics of surgical technique, presence of infection and the character of the after-care. Many would justifiably add to this list the factor of luck.

Innumerable agents have been laced around tendons to prevent adhesions from forming while the tendon ends are uniting. The following materials have been tried, either clinically or experimentally: nylon, cellophane, teflon, polyethylene, millipore, ivalon, silastic, stain-

less steel and vitallium. Following placement of synthetic blocking tubes, granulation tissue formed by peritendinous tissue must grow beneath the edges of the tube at both ends and advance slowly along the surface of the tendon. Only when this proliferating tissue reaches the anastomosis site does any healing occur. Unfortunately, thick, vascular, limiting adhesions form at either end of the tube. These adhesions never become filmy and mobile. Since nutrition is compromised by the tube itself, various degrees of avascular necrosis and karyolysis** of the tendon occur. This is especially a problem when a free tendon graft is used.

Somehow the effects of the eventual and inevitable tendon adhesions must be minimized. It has been shown repeatedly that adhesions occur only at suture sites and at points where the integrity of the tendon surface is broken. An uncompromised and untraumatized glistening tendon surface will not adhere to surrounding tissue. The task is therefore to handle the tendon with exquisite care, to breach the integrity of its surface only at suture sites and with only the most non-reactive materials. By following the basic principles of tendon repair with continual emphasis on gentle atraumatic technique one can expect the inevitable adhesions to be few in number and ultimately filmy and loose.

DORSEY "FLU-GRAM"

DON'T BE LULLED BY RELATIVE LACK OF FLU LAST WINTER. THIS WINTER BE PREPARED: WHEN THE COMPLAINTS ARE COUGH AND CONGESTION, YOU CAN RELIEVE THESE SYMPTOMS WITH TUSSAGESIC TABLETS. ONE TIMED-RELEASE TABLET AT MORNING, MIDAFTERNOON AND BEDTIME BRINGS UP TO 24 HOURS' RELIEF FROM TROUBLESOME COUGH AND STUFFED AND RUNNY NOSE. TUSSAGESIC IS THE FAMOUS TRIAMINIC FORMULA, PLUS THREE OTHER PROVED CONSTITUENTS. MAKES PATIENTS MORE COMFORTABLE. FAST. ASK YOUR DORSEY REPRESENTATIVE FOR SUPPLY OF STARTER SAMPLES, OR IF FLU IS ALREADY EPIDEMIC, PHONE COLLECT. SEE BELOW.

each **Tussagesic**[®] timed-release tablet contains:

Triaminic [®]	50 mg.
(phenylpropanolamine hydrochloride 25 mg., pheniramine maleate 12.5 mg., pyrilamine maleate 12.5 mg.)	
Dextromethorphan hydrobromide	30 mg.
Terpin hydrate	180 mg.
Acetaminophen	325 mg.

Dosage: Adults—1 tablet, swallowed whole to preserve timed-release feature, in morning, midafternoon and at bedtime. **Side effects:** Occasional drowsiness, blurred vision, cardiac palpitations, flushing, dizziness, nervousness or gastrointestinal upsets. **Precautions:** The patient should be advised not to drive a car or operate dangerous machinery if drowsiness occurs. Use with caution in patients with hypertension, heart disease, diabetes or thyrotoxicosis.

Management of Acute Suppurative Sinus Disease

DR. HILL'S* TITLE specifies suppurative sinus disease. This is particularly important in view of the widespread advertising of medications for "sinus miseries" appearing in television, radio, and the press. One of the primary requirements for treatment of sinusitis is diagnosis, and the primary requirement for diagnosis is to differentiate actual disease of the sinuses, whether suppurative or allergic, from the myriad complaints of "sinus" which come to the attention of the physician. These complaints are based on various headaches, fatigue, stuffy nose, dryness in the nose from poor humidification, mucus in the throat, and various neuroses and inadequacies. Differentiation is important because, as stated by Dr. Hill, suppurative disease of the sinuses responds favorably to treatment. Allergic disease responds less favorably. The various symptoms that the

patient attributes to the sinuses as a result of exposure to advertising claims cannot be expected to respond to treatment for an infection or an allergy. Considerable effort on the part of the physician in taking an accurate history and, in many instances, physical examination or laboratory examinations or both are necessary to differentiate the causes of these various symptoms, so that effective treatment may be applied. In many instances, reassurance and an explanation of the nature of the nose and its function is all that is required. In others, treatment for headache or for nervousness may be in order if the patient is to be relieved. It is unfortunate that the advertising of over-the-counter drugs is not under the same stringent control as advertising of prescription products; much misunderstanding and apprehension might thus be avoided.

You May Be Right

Your Stature

In your Soliloquy, *For Whom Does the Bell Toll*, in the July issue of MINNESOTA MEDICINE you wrote: The dietary inadequacies of three or four generations ago undoubtedly contributed to the smaller stature of our grandparents as compared with the increased stature of the draftees in World War II.

Did you mean to imply that taller stature is *per se* an evolutionary asset to man? I have yet to meet up with a biologist who considers greater human stature as having survival advantage. Aside from running faster and reaching higher, capacities no longer required by man's natural environment, does taller stature correlate with increased economy and efficiency in the human body?

In fact, may not greater stature be regarded as a biological over-specialization that could run *Homo sapiens* into an evolutionary dead end and possible extinction? Witness the dinosaurs who succumbed to overspecialization: a prime example of a species that became extinct when its food supply failed to remain commensurate with its size.—E.G.R.

EDITOR'S NOTE: Under ideal circumstances—vitamins, minerals, proteins and a host of other things, from birth through the growing period, presuming also that the endocrine balance within the body was also ideal—I expect a species would attain a rather fixed stature in accordance with their basic genes. It might get rather involved, though, if one were to amalgamate the black, white, yellow, and brown races.

In the human with 22 genes and presuming 1000 characteristics to produce a perfect giant, the possibility of another would be $\frac{1}{2}$ of 22 to the thirteenth power. That's in the trillions.

Work and Fatigue

Thanks so much for the Editor's Soliloquy pertaining to work and rest. You hit the nail squarely on the head with every sentence.

Soon after the philosophy of less work and more rest was getting under way a few decades ago, I prepared a manuscript entitled "Work and Fatigue." I am sure that honest labor from the time of John Smith in Colonial days to the present (1929), will continue to be the main cause of prosperity among people everywhere in the world.

J. A. Meyers, M.D.

EDITOR'S NOTE: I wish to quote from that manuscript, in effect:

"To prescribe discontinuance of work and a long period of bed rest for one who has previously been healthy is worse than the most bitter medicine. Unfortunately the idea is extant that work is harmful; that it jeopardizes health. This perhaps is partially responsible for a great deal of dissatisfaction and has led to unreasonable demands for reduced working hours. 'An idle brain is the Devil's work shop' applies as well as to an idle body. To labor to the point of fatigue is not harmful to the healthy body and mind; in fact, it in-

duces better relaxation and sleep. But the person who spends six hours in ordinary work and devotes the remainder of the day to idleness or worthless recreation is loyal neither to his nation nor to his mind and body.

"At present [1929] there is a good deal of complaint about 'hard times.' I am convinced that much of the difficulty is due to the fact that many are not devoting themselves to their work as diligently as they should, nor as assiduously as they did a decade or more ago.

"I do not recall ever having seen a healthy person harmed by work, but I have seen many who have blamed their work for their illnesses. The Creator very wisely protected us from overwork by endowing us with a sense of fatigue, which usually impels us to discontinue labor before we overexert our muscles to the point of harm.

*"We continually see people who, at the age of thirty-five or forty, appear older than others at the age of sixty or seventy. They are badly stooped and their mentality has deteriorated; they do not remember well; they do not converse as freely as they did in the past; they do not enjoy reading; in fact, life has become more or less a bore and a burden to them. They have allowed their mind and muscles to become flabby and useless because of inactivity."**

Jay A. Meyers has no doubt been a stimulus to more men than he realizes, currently.

*The Trained Nurse and Hospital Review, May, 1929.

Army of Friends

Blood donors are treated with great concern in the Soviet Union. Their health and living conditions are thoroughly investigated. Donorship is honored. The outstanding social service of those who give their blood to the sick, is rewarded with "Honored Donor" badges.

In 1919 there was one donor in the entire Soviet land . . . Now there are tens of thousands. It is a veritable army of men and women with a highly developed sense of duty and fellow feeling, an army of friends.

Blood transfusion is organized on a great scale. Even pre-war figures speak of this. There were 2,433 blood transfusions in 1932, 22,160 in 1935, and 100,143 in 1938, while in 1940 their total jumped to 226,000.

Wide use of conserved blood was first made in 1934, when 4,429 of the total 12,942 transfusions, or 26 per cent, were made with conserved blood. In 1938 this figure climbed to 70 per cent, and in 1940 to 90 per cent.

In the Soviet Union scientists and entire institutions carry on their work under exceptionally favorable conditions. Like all public health facilities, blood transfusion has always been a matter of state concern.

The Moscow Institute of Hematology and Blood Transfusion, the first of its kind in history, was founded in 1926. In its wake similar institutes were established in almost all the major Soviet cities—Kharkov, Leningrad, Tbilisi, Minsk, and others.

In 1941, the U.S.S.R. had about 1,500 institutions specializing in blood transfusion. Today every single point in the Soviet Union, including the Far North, has transfusion facilities.

Like all other forms of medical treatment, even the most complicated blood transfusions are made free of charge. Their cost is covered by the state budget.*

The Editor's Soliloquy

Evolution or Revolution?

Two Feet in the Stirrups: Physician or Technician

MANY EXCELLENT technical operators have been produced in experimental laboratories from high school graduates. These technicians have mastered the steps of medical and surgical procedures and know how to perform well at the direction of their mentor. Nurses and others have learned to do accurate laboratory routines and execute the infinitely precise details of an intensive care or cardiac recovery room in accordance with the directions of a knowledgeable physician.

The majority of technicians know only the rudiments of medical or surgical indications for the procedures they perform so competently and even less about the pathologic processes involved.

The glory of these dedicated employees is unsung in the annals of medical history. They simply work a 40-hour week, collect their bi-monthly check and receive their pay raises in accordance with their tenure. Such is the character of the technician.

The physician, like the technician, performs with precision and proficiency. But no follower he! His role is that of initiator, for therein lies his dharma.* The doctor's long and arduous working hours do not fit into a convenient schedule and his monetary reward is no more than commensurate with the value of his service to his community. His capacity for infallible decision and judgment must be tempered to the quality of the finest steel through diligent study and adequate training in the basic sciences, metabolic processes, and their potential pathology. He must be capable of meticulous evaluation of abnormal physiologic signs from hour to hour; he must recognize almost instinctively the surgical risks and the medical alternatives thereto.

He must also be adept in the psychological management of the patient—in and out of balance—both individually and family-wise. These qualities are integral to his makeup—unadorned with splash and splendor and often unidentifiable to the casual observer. Such is the character of the physician.

The categorical distinction between the technician and the physician lies in the extra-dimensionality of the doctor's sphere: in his art which consists of a distillate derived from the twin disciplines: the scientific and the humanistic. Only a study of the liberal arts, requiring time and maturation, can furnish the broader outlook and deeper insight so invaluable and indispensable to a doctor dealing with human nature as well as with diseased bodies.

Change is ubiquitous and perennial; but let us not be under the illusion that change always represents progress. It is that extra-dimensionality that Medicine must not forfeit in a quest for earlier specialization. If we can keep both feet firmly and confidently planted in the stirrups* and be prepared to advance, then it is conceivable that the next 50 years could duplicate the past 50 which have already produced more advances in medicine than all the preceding half-centuries.

Granted, however, that some changes may be desirable, it would seem unnecessary to start a revolution in medical education in order to rectify a few current teaching errors.—Carl O. Rice, M.D.

THE S.S. HOPE is a floating medical center — a fully staffed and fully equipped modern hospital which is the vehicle by which Project HOPE fulfills its mission of carrying American medical treatment and training to foreign lands where such help is not only needed but wanted. Project HOPE is a nongovernmental, nonprofit organization which is financed solely by voluntary contributions from individuals and private enterprise of North America.

THEIR HOPE — Although thousands of natives are treated on ship and ashore, the primary objective of HOPE is teaching. Every HOPE physician, nurse, or technician has his local counterpart who is trained to continue modern treatment after the ship leaves. It is a seeding process which multiplies in the underdeveloped country to improve the health of its citizens and thus their productivity and thereby creates a progressive economy and a higher living standard. The kind of economy in which communism cannot thrive!

OUR HOPE — HOPE — an acronym for Health Opportunities for People Everywhere — is a young Project only in its fourth year of operation but already the evidence is incontestable that its missions are highly successful, not only in the interchange of medical knowledge but also in promoting international friendship and goodwill.

YOUR HOPE — HOPE's basic professional staff of nurses, technicians, etc., are paid a nominal salary but most of its teaching physicians and dentists serve without financial compensation. This makes it not only our most successful foreign aid program but also our cheapest. Nevertheless, private contributions are essential. You may participate by drawing and mailing a check to:

C. Walton Lillehei, M.D.

On October 7, 1967, Dr. C. Walton Lillehei was honored at a Testimonial Dinner at the Hotel Radisson, Minneapolis, by his present and former fellows in cardiovascular surgery, prior to his assuming the position of Lewis Atterbury Stimson Professor of Surgery and Chairman of the Department of Surgery, Cornell University Medical Center—New York Hospital on November 1st.

The esteem with which Doctor Lillehei has always been held by his former fellows was exemplified by many, such as Dr. Alberto Spoerer (Santiago, Chile) and Dr. Denis Thompson, (Bulawayo, Rhodesia) who traveled great distances for the occasion.

We Extend to Him this Tribute

I am happy to be here with these interesting surgeons. I am proud to have been included on this occasion. I feel humble to sit among you, and as I meditate thinking of you, Walt Lillehei, I wish that I had known more intimately some of your illustrious peers, predecessors though they be.

I wish I had known *Ambroise Pare*, a patient man, the Prince of Surgeons, back in the 16th Century when he reinstated in France the practice of ligaturing instead of cauterizing blood vessels after amputation. If I had been there I would have defended him vigorously against the opposition of his reactionary colleagues. It would have been interesting to see him take exception with the King of France, who was an ardent advocate of the value of the stag stone as an antedote against snake bite, and who then, after suggesting that the King try the experiment on some of his condemned prisoners, found that the experiment failed.

I wish I had known the *industrious William Harvey*, the father of physiology, who, in 1628, announced his revolutionary discovery that the blood circulates, leaving the heart by the arteries and returning by the veins. From

NAME

ADDRESS

AGE

M.M.

that historic day on doctors knew that in order to prevent bleeding from the vessels, the arteries had to be ligated toward the heart and the veins away from the heart.

I am sure that I could have enjoyed the *indefatigable meticulous technician, John Hunter*, who in 1785 carried out his bold operation on an aneurysm of the popliteal artery, postulating its effectiveness based on earlier experiments on the antler of a deer, in which he had demonstrated the collateral circulation. I would have enjoyed visiting his menage where he kept a conglomeration of animals, dead and alive, for purposes of observation, examination, experimentation and anatomical dissection.

I should like to have known the *far-sighted Louis Pasteur* and to have joined him in his laboratory during the 1860s, when he looked through the microscope and then carried out experiments to prove that the micro-organisms causing disease were not self-generating, thus leading to the use of carbolic acid as an antiseptic in surgery; this in turn causing the *courageous Joseph Lister* to crusade for antiseptics against the opposition of the non-Listerians who ridiculed him for dousing his patients, spraying the walls, soaking his instruments and hands with disinfectants.

I could have enjoyed knowing the *versatile Swiss surgeon, Theodore Kocher*, who, in the 1880s, made surgery on the thyroid safe, and who in 1909 was the first surgeon to be awarded the Nobel Prize, for his monumental work on goiter.

I wish I had known the *ingenious innovator, Eldorado Bassini* of Padua, in 1888, when he performed one of the first anatomical procedures for the cure of hernia, and after the operation tickled the throat of his patients in order to make them cough and gag to test the strength of his surgical repair.

These men were pioneers, each in his own field; they were ingenious, versatile, courageous, indefatigable, far-sighted, industrious, and patient men. I predict that one of my progeny will some day be reciting a similar list of historical luminaries in the field of surgery much as I have done this evening, boasting pridefully that their great-grandfather knew intimately, shook the hand of, and visited with one of the great pioneers of my time, a man who possessed all of these great qualities and received recognition—the man who made surgery on the heart safe and a common, everyday procedure: C. Walton Lillehei! To you, Walt, a Salute!—Carl O. Rice, M.D.

False Trails and Byways

The healing art was bound to fall into errors. It could not avoid them, for the remedies at its disposal were inadequate for the tasks it was set. The tasks were not shelved—but discharged by makeshift solutions which became sanctioned errors.

But that is the way of science: "We must exhaust the error—and often the idiocy—before we can work our way towards the beautiful goal of calm wisdom."

—Schiller

Temperature

Very high and very low temperature extinguishes all human sympathy and relations. It is impossible to feel affection beyond 78 degrees, or below 20 degrees of Fahrenheit; human nature is too solid or too liquid beyond these limits.

Curbstone Consultation

QUESTION: One of my patients, a 56-year-old man with Laennec's cirrhosis, was admitted to the hospital with jaundice, ascites and the characteristic clinical and laboratory findings of advanced hepatic cirrhosis. He improved on a regimen of diet and the circumspect use of diuretics. Today, after two weeks of steady improvement of clinical and laboratory parameters he suddenly developed high fever. There is no sign of urinary tract, pulmonary or central nervous system infection. There was no change in therapy and no manipulation which could have provoked this new event. What might be the nature of this new episode?

ANSWER: It is not unusual for patients with advanced cirrhosis to develop seemingly spontaneous bacteremia. Usually this is a gram-negative bacteremia and its occurrence in cirrhotics is explained as follows: Intestinal bacteria escape from the bowel in normal individuals by way of the venous and lymph channels, but they are effectively intercepted by the reticuloendothelial system of the liver. In the cirrhotic patient, however, the liver can be circumvented by way of the collateral circulation, thus presenting a ready and ever-present threat of gram-negative bacteremia.

We have to assume that this happened to your patient. After you have obtained aerobic and anaerobic blood cultures, you should lose no time in treating this presumed gram-negative bacteremia with a drug, which should cover most or all of the enteric organisms. At the present time a combination of Kanamycin and Cephalothyn would serve this purpose, until blood cultures have established the precise nature of the bacteremia and thus permit more specific therapy. At the first sign of hypotension appropriate measures should be met for the control of endotoxin shock.

H. H. Zinneman, M.D.
Minneapolis, Minnesota

What's on your mind—if you'll forgive the overstatement.

The Viewing Box

Shoulder Mass in an Infant

Clinical History

THIS INDIAN female infant was first seen at the age of six weeks because her mother had noted that she suddenly was not moving her right arm. There was no other significant history. Initial examination of the patient disclosed irritability, a fever of 102° , and a large, firm, tender mass over the right shoulder posteriorly to include the axilla. She refused to allow the examiner to move her right arm and moved it herself very little.

Pertinent laboratory data included a leukocytosis of 17,000 with a normal differential, a sedimentation rate of 113 (mm/hr.), and an alkaline phosphatase of 70 (King-Armstrong units).

An electromyogram performed early in the hospital stay showed findings consistent with a right brachial nerve palsy.

What is your diagnosis? (See next page.)

Fig. 1—The initial chest film (7/24/67) discloses a soft tissue mass in the right shoulder. There is an appearance suggestive of early subperiosteal resorption of bone (arrow) on the axillary border of the scapula just below the glenoid. Of no consequence is a healing left clavicular fracture which was traumatic in origin.

Diagnosis: Infantile cortical hyperostosis (Caffey's Disease).

Fig. 2—A subsequent chest film (8/22/67) shows a markedly hyperostotic right scapula which has practically lost its original anatomic form. Note the new born formation (arrows) in the mandible, clavicles, right ribs and the opposite scapula.

Fig. 3—The last film (10/18/67) now shows a marked thickening of the clavicle and several of the ribs. The scapula is still deformed, but there has been considerable resorption of the hyperostoses.

This benign condition, first reported by Caffey and Silverman in 1945, may affect much of the skeleton and its adjacent fascia and muscles. There is no sexual or racial predilection. The average age of onset is nine weeks, no cases reported having begun after nine months of life. Almost all of the patients will commonly have hyperirritability, fever, swelling of the soft tissues and polyostatic involvement with cortical new bone formation.

Changes have been reported in most bones other than the phalanges and vertebrae. Most commonly affected are the mandible, clavicles and ulnae. If confined to only one bone other than the mandible, the picture should be considered due to trauma unless proved otherwise.

The early finding suggesting sub-periosteal resorption of bone in the scapula is of particular interest in this case. Caffey¹ states that this has not been previously observed. When seen in its early stages, Caffey's disease unilaterally involving the scapula (which is usually the case) can be confused with osteosarcoma.

The electromyogram findings suggesting a brachial nerve palsy are uncommon. This could be the result of axillary inflammation and mass effect. The electromyogram reverted to normal when the patient improved clinically.

Although the clinical history and roentgenograms are usually characteristic for this entity, one might include scurvy, rickets, osteomyelitis and trauma in the differential diagnosis.

The disease is usually self-limiting with clinical and radiographic findings reverting to normal within a period of several months. Steroids have been used in the treatment of the disease with success, as in this case. Caffey places all of his patients on a course of steroids.

Medical Men on Postage Stamps

Walter Reed (1851-1902), American army surgeon, sanitarian and bacteriologist, who during the Spanish-American war was sent to investigate a typhoid epidemic among the U. S. troops and who in 1900 headed a commission to Havana to investigate its etiology, was honored for his achievements by a commemorative postage stamp issued by the U. S. in 1940. Reed also did valuable research work on cholera and erysipelas, but his main contribution to medicine was his theory that yellow fever was transmitted by a mosquito.

Julius Wagner-Jauregg (1857-1940), Austrian neurologist and psychiatrist, whose malarial inoculation treatment of paresis was 30% successful in a disease previously fatal, and who also made valuable contributions in the fields of cretinism and other thyroid diseases, was honored by an Austrian postage stamp issued in 1957.

Laboratory Diagnosis of Rubella

The Division of Medical Laboratories of the Minnesota Department of Health is now ready to provide serologic tests for rubella. Acceptance of blood specimens for rubella antibody determinations will be limited to the following situations:

1. Determination of immune status of pregnant women (first trimester) with documented exposure to rubella. A single whole clotted blood specimen must be obtained within one week after exposure.
2. Confirmation of rubella infection in pregnant women (first trimester). An acute whole clotted blood specimen must be obtained within the first three days of rash and a convalescent whole clotted blood specimen, collected seven to ten days after the acute specimen, is required.
3. Investigation of presumptive complications of rubella (encephalitis, etc.), especially in young children. For this purpose paired acute and convalescent whole clotted blood specimens are required. Specimens from adult males or from children other than those who can qualify in group 3, must be declined at the present time.

Containers for the submission of whole clotted blood are the same as those currently in use for submitting specimens for virus antibody studies. Additional containers are available on request from: Minnesota Department of Health, Division of Medical Laboratories, University Campus, Minneapolis, Minnesota 55440.

It is important to all concerned that specimens be accompanied by completed data cards identifying the patient, giving clinical diagnosis, date of onset of illness, etc.

Division of Medical Laboratories

Anesthesia Through Will Power

The use of the will to ease pain must have seemed to verge on the miraculous to those who could not possibly know that we can condition our reactions and responses to a painful stimulus.

Something like this had been demonstrated by the seventeenth century French mathematician, Blaise Pascal. Suffering intense pain from a facial neuralgia, he found himself unable to sleep. Tossing in his agony, he remembered that Seneca, the stoic philosopher of Rome, had once commented: "The more the attention is fixed on the cause which produces pain, the more its intensity is increased; the more a man stands away from it, the more relief he gets."

In desperation, Pascal decided to test this and began to concentrate on a problem in geometry that had puzzled scholars for years. In the course of his intense preoccupation he forgot his pain and solved the problem in one night.

Later, when he was asked to what use he would put his mathematical discovery, he replied: "None. But it was a good cure for a bad night."*

Neurological Conference

Paresthesias* in an Elderly Patient

Medical History

Doctor Ordean Torstenson**:

This 69-year-old man was first seen in our New Medicine Clinic on December 7, 1966, with a chief complaint of a burning feeling within his mouth and in his left leg, which had first appeared in January, 1965, following a hospitalization for pneumonia. The possibility of an allergic condition was considered at that time, but an allergy evaluation was negative. This discomfort has persisted with the same intensity for the past two years. Occasional mouth washes have relieved the burning in his mouth somewhat for short periods. The burning sensation in his left leg originally was present only in the anterior left hip but subsequently spread to involve his entire left leg. He obtains slight relief of his leg discomfort when walking.

The patient stated that during the past two years he has had numerous hospitalizations at St. Luke's Hospital and Miller Hospital for these complaints; but no attempted treatment has afforded any significant relief. Presently he is taking no medications except for one Contac pill daily for sinus drainage, and Maalox for a peptic ulcer condition which he has had for two and one-half years. Other complaints include shortness of breath on exertion and occasional sharp chest pain when breathing deeply. An increased urinary frequency also bothers the patient at times.

Physical Examination

Physical examination revealed an elderly man with a slightly protuberant abdomen. Although he appeared to be somewhat anxious, he was in no actual distress. His blood pressure was 160/100 mm.Hg. and his pulse 90 per minute. In his mouth there were three canker sores and a questionable area of leukoplakia on the lateral aspect of his left upper alveolar ridge. A few dry rales were present in the base of his left lung. Rectal examination revealed non-inflamed external hemorrhoids. The skin over his lower legs was moderately erythematous and shiny, and numerous small varicosities were present.

Neurological Examination

The neurological examination revealed no definite findings. Vibration sensation was somewhat reduced in his lower extremities, and a positive Patrick's sign was present in the left leg. Mentally the patient showed a mild memory deficit and he was totally incapable of subtracting serial sevens from 100.

*See Test Your Word Score Page 1823.

Neurological Conference held January 12, 1967. These conferences are an integral part of the Comprehensive Clinic Program at the University of Minnesota Hospitals.

**Student doctor, University of Minnesota Hospitals.

Laboratory Findings

Laboratory examination revealed a hemoglobin of 15.4 grams% with a normal hemogram. The urinalysis was unremarkable, BUN 21 mg.%, and a glucose tolerance test was within normal limits. In 1959 the patient had had an abnormal EEG characterized by diffuse theta activity. A repeat electroencephalogram in January, 1967, showed similar slowing occurring bilaterally in regular and irregular runs of activity mainly in the anterior regions of the head. An electrocardiogram was suggestive of an anterior septal myocardial infarct. An upper G.I. examination revealed a small hiatus hernia with gastroesophageal reflux, considerable deformity of the pyloroduodenum and a small duodenal diverticulum in the descending portion of the duodenum.

Initial Impression

Dr. Robert W. Soll:*

This patient has had fairly extensive medical care during the past seven years for numerous complaints, none of which had any particularly localizing value. Furthermore, none of the tests which we have done now have contributed any further insight into the cause of his chief complaint, which is a burning sensation in his left leg and his mouth. The patient's slow mentation and mild memory deficit together with a diffusely abnormal electroencephalogram may be the only significant findings that we have. Together these suggest the possibility of a cerebral degenerative process. Although the BUN is slightly elevated, the patient has no other obvious evidence of renal disease. This will have to be investigated further.

Psychological Evaluation

Mr. William Gayton:**

Several tests were administered in order to evaluate intellectual functioning, personality processes and the possibility of brain damage. In regard to intellectual functioning, the patient shows a discrepancy between his verbal and performance abilities; on the Binet Vocabulary he has an M.A. of 14.7, giving him an approximate I.Q. of 95, which is within normal limits; on the Porteus Maze, which is a perceptual motor task, he has a test age of 11 and 1/2 years, reflecting an I.Q. of only 82, which is in the dull-normal range. Such a discrepancy between verbal and performance measures is not inconsistent with his present age since performance type behavior does decline with age. It should be pointed out, however, that this type of discrepancy is also very frequently found in brain-damaged patients. In those tests to evaluate cerebral dysfunctioning the patient shows deficits in short-term memory and visual motor coordination. Although these tests correlate with his age, I.Q., and education, they would probably be more significant if they were found in a younger person with a higher I.Q. and a broader educational background. The personality evaluation as conducted by the Minnesota Multiphasic Personality Inventory suggested a mildly neurotic profile with depression and somatic overconcern. The depression is most likely a response to the physical pain which he has been experiencing over the past few years. He was somewhat rigid and inflexible on this test, tending to resist any psychiatric explanation of his problem. Correspondingly, he would probably be very resistant to any intervention of a psychotherapeutic nature.

In summary, his most marked deficits were in the perceptual motor tasks and tasks requiring short-term memory, deficits which fall into the brain-damaged category if scored according to the norms. If age, past educational history and other tests of I.Q. are considered, however, the significance of these findings is somewhat questionable.

*Neurologist, University of Minnesota Hospitals.

**Clinical psychology trainee, University of Minnesota Hospitals.

Social Service Evaluation

Miss Helen Kretchmer:*

The patient seems to be a meticulous, conservative individual with expectations of himself that he is unable to fulfill. He hasn't been able to work since 1961 and has become conscious of the cost of his medical care and his dwindling savings. He was retired on disability about the time that he developed an ulcer. He had considered going elsewhere for his medical problems, but his family physician persuaded him to come here because it would probably be less expensive for him.

After finishing part of the 8th grade, the patient quit school because he was the oldest of eight children and was needed on the farm. During World War I at age 17 he enlisted and was able to complete part of the 9th grade while in service. The ship on which he was stationed was sunk, but he was rescued. As a result of a service-connected back injury he received a pension of \$80.00 a month. After service he did some drafting but finally began working in a shipping department as an assistant foreman. The patient underwent considerable nervous tension on this job, a factor which may relate to his eventual development of an ulcer. During the past few years he has been helping around the house and doing a little yard work.

Both the patient and his niece convey the impression that he has always been a rather nervous man. She commented on a book written by a psychologist, which made her feel that her uncle was a neurotic. When she mentioned this to the patient, he became very angry with her. She also mentioned that the patient's father had similar symptoms of burning of the mouth and drooling when he was 52 years of age. After being placed on some type of tranquilizer for a couple of months he recovered. Her own father also had had similar symptoms at age 69 and responded to the same treatment. According to his niece, the patient has always been very restless; consequently, it is difficult to distinguish his present troubles from his past problems.

Neurological Evaluation

Dr. Soll:

Although widely separated in location, the paresthesias which the patient feels in his mouth appear to be similar symptomatically to the burning sensation in his left thigh; however, I know of no way to relate them anatomically. Paresthesias do occur in many conditions, such as traumatic peripheral nerve lesions, multiple sclerosis, tabes dorsalis, and pernicious anemia. *Arteriosclerosis* has been known to be associated with paresthesias, probably the result of an ischemia of the peripheral nerves. Supporting the possibility of a diffuse arteriosclerotic involvement is the abnormal electroencephalogram. Although the changes on the electroencephalogram are not necessarily typical of arteriosclerosis, this possibility certainly exists. In addition, various lesions of the spinal cord, brain stem, thalamus and parietal lobe have produced paresthesias. Unfortunately there are no focal findings to help localize the specific cause in this patient's case.

Often the obvious cause may be an irritative pathological process, but in many instances it may be quite inconspicuous. Clinically, paresthesias developing during the course of a neuropathy such as occurs in *alcoholism or vascular insufficiency* often appear initially after the neuropathy has become well-

*Supervisor, Social Service Department, University of Minnesota Hospitals.

established and convalescence is under way. This might also be likened to paresthesias that develop in an extremity after it has "gone to sleep."

Finally, there is the possibility that the patient's symptoms have a *psychogenic* component. I feel that the patient may be over-reacting to his symptoms. He probably also has had some reduction in intellectual functioning as manifested by his inability to subtract serial sevens from 100 or name the recent presidents. During his clinic visits he has had a great tendency to ramble on about his symptoms or problems.

Although the patient's real problem may be the result of vascular disease, the best treatment would be to reduce his nervousness and anxiety with tranquilizing medications. Hopefully his numerous minor complaints would also subside if he were calmer. Rather than telling him that he is on a tranquilizer, we can simply explain that he needs to be on a special medication to reduce the nerve activity which is causing the burning. If symptoms continue to worsen in the continued absence of any good localizing sign, pneumoencephalography and examination of the spinal fluid could be done as a further diagnostic procedure. In degenerative cerebral diseases, evidence of an elevated spinal fluid protein and cerebral atrophy may be elicited.

Patient is Interviewed.

Dr. Soll:

For what reason did you have to quit work?

Patient:

I had ulcers and a spastic nervous system which the doctors told me was probably the result of my stomach trouble. I could have continued working longer, but one day I passed out at work and couldn't speak. On my way to the hospital in an ambulance my speech returned.

Dr. Soll:

Did you have any weakness?

Patient:

No, only my speech was impaired for a while.

Dr. Soll:

What were you doing at the time that the spell occurred?

Patient:

It happened shortly before quitting time in the afternoon. I began feeling weak and sat down. Apparently I passed out, but when I awoke I was just as normal as before. Following this the company told me to retire. Although the union said they would fight it for me, I decided to quit because I thought the same thing might happen again. What I am concerned about now is the burning in my mouth. If you people tell me that I am mentally disabled or something like that, you are wrong. My faculties are just as good now as they were 30 years ago. I was very much amazed about the tests. I may have a nerve condition—I am not saying that I haven't something minor. Naturally my brain doesn't function as it did years ago. I don't have a large education but I think my body and brain work in proportion for my age with an average education. I have no heart condition and my blood pressure is okay. My father had trouble similar to this and got over it in a few months.

Miss Kretchmer:

You do not feel that you should take public assistance, but you have several debts you are worried about.

Patient:

I am paying \$69.00 a month on our house, as well as trying to keep up the car. We owe our doctor \$400, not counting the medicines. If I have to go on another year like this, I'd rather be dead. I lose sleep and so does my wife.

Patient leaves the conference room.

Discussion and Recommendations**Dr. Soll:**

I would like to start the patient on a tranquilizer. This could be supplemented with a mild antidepressant medication and also with a sedative for sleep, if necessary.

Mr. Gayton:

How might the tranquilizer influence the type of depressive behavior which his Minnesota Multiphasic Personality Inventory indicated?

Dr. Soll:

I don't believe it will affect the depression very much, but it may alleviate some of his anxiety and nervousness.

In regard to the episode of unconsciousness which he had in 1961, it is interesting to speculate that he may have had a transient cerebral ischemia at that time. This would help support the possibility of a cerebrovascular condition.

Mr. Gayton:

Subtle psychological changes reflecting brain damage might be revealed by a special battery of psychological tests developed by Dr. Manfred Meier in the Neuropsychology laboratory.

Dr. Soll:

Frequent visits to the neurology clinic also would help to reenforce the medical therapy.

Addendum

The patient has been treated in the above manner and there has been significant improvement in his symptomatology during the past nine months.

Robert W. Soll, M.D.
Chairman,
Adult Community Services

Participating in the conference were: Student Doctor Ordean Torstenson; Miss Helen Kretchmer, Supervisor, Social Service Department; Dr. Robert Soll, Neurologist and Mr. William Gayton, Clinical Psychology Trainee.

LOW-BACK PAIN

A CONSERVATIVE, FOUR-POINT PROGRAM

The low back pain that is most frequently seen in general practice is mechanical in nature, i.e., postural back pain, joint dysfunction and acute back strain.^{1,2} For this type of discomfort, a conservative regimen is usually sufficient to relieve aches and pains, and to help keep the patient functioning. Components of this basic program include:

1 Bed "If the patient is in the pain-spasm-cycle... there is no alternative or substitute for absolute bed rest..."³

2 Board "Boards should be ordered under the mattress... these boards act by immobilizing the spine..."⁴

3 Heat "A very valuable method of applying heat at home is a prolonged hot bath..."⁵

4 Robaxin®-750 (methocarbamol, 750 mg. capsule-shaped tablets) A well-tolerated⁶ skeletal muscle relaxant, methocarbamol helps relieve spasm "...without interfering with normal tone and movement."⁷ And there is little likelihood of sedation.⁶

Indicated for relief of skeletal muscle spasm. Contraindicated in hypersensitive patients. Side Effects (lightheadedness, dizziness, drowsiness, nausea) may occur rarely, but usually disappear on reduced dosage. Hypersensitivity reactions develop infrequently. See product literature for further details. Also available: Robaxin® Tablets (methocarbamol, 500 mg.) Robaxin Injectable (methocarbamol, 1 Gm./10 cc.)

Compound with Codeine remains unchallenged.

BURROUGHS WELLCOME & CO. (U.S.A.) INC., Tuckahoe, N.Y.

When the talk turns to oral contraceptives, it makes medical sense to remember low-dose Norinyl-1.

(norethindrone 1mg, $\bar{c}$ mestranol 0.05mg.)

Turn page for contraindications, precautions and side effects.

Reduction of oral contraceptive dosage to the lowest effective levels is a well-accepted principle of conservative medical practice. In keeping with this view, Norinyl is now also available as Norinyl-1, containing exactly one half the previous dosage of norethindrone and mestranol. Clinical experience has established that effective fertility control can be achieved with the same degree of reliability and safety with new Norinyl-1 when taken as directed.

What about switching patients from higher dosage forms?

In transferring patients to low-dose Norinyl-1 from higher-dosage oral contraceptives, some breakthrough bleeding may occur in the early cycles. In the majority of cases the bleeding episode is mild and self-limited. The long-term advantages of the lower dosage form should be weighed against the inconvenience of possible breakthrough bleeding in the individual patient.

Prescribing Information

Contraindications: Patients with any symptoms or history of thrombophlebitis, pulmonary embolism, liver dysfunction or disease, carcinoma of breast or genital organs, or undiagnosed vaginal bleeding.

Warnings: Discontinue medication pending examination if there is sudden partial or complete loss of vision, proptosis, diplopia or migraine. If examination reveals papilledema or retinal vascular lesions, medication should be withdrawn. The safety of Norinyl-1 in pregnancy has not been demonstrated. If a patient misses two consecutive periods, pregnancy should be ruled out before continuing the medication. If she has not adhered to the prescribed schedule, pregnancy should be considered at the first missed period. Active ingredients of oral contraceptives have been detected in the milk of mothers who received these drugs; the significance to infants has not been determined.

Precautions: Pretreatment physical should include examination of the breasts and pelvic organs, as well as a Papanicolaou smear. If endocrine or liver function tests are abnormal during therapy, repeat tests are recommended after the drug has been withdrawn for two months. Following administration of drug, preexisting uterine fibromyomata may increase in size. Careful observation and caution are required for patients with symptoms or history of epilepsy, migraine, asthma, cardiac or renal dysfunction, cerebrovascular accident, psychic depression, and diabetes. In cases of undiagnosed vaginal bleeding, adequate diagnostic measures are indicated. Possible long-term effects of the drug on pituitary, ovarian, adrenal, hepatic or uterine function must await further studies. The physician should be alert to the earliest manifestations of thrombophlebitis and pulmonary embolism. The drug should be used judiciously in those young patients in whom bone growth is not complete. The age of the patient constitutes no absolute limiting factor, although treatment with Norinyl-1 may mask symptoms of the climacteric. The pathologist should be advised of Norinyl-1 therapy when relevant specimens are submitted.

Side Effects: The following have been observed with varying incidence in patients receiving oral contraceptives: nausea, vomiting, gastrointestinal symptoms, breakthrough bleeding, spotting, change in menstrual flow, amenorrhea, edema, chloasma or melasma, breast changes (tenderness, enlargement and secretion), change in weight (increase or decrease), changes in cervical erosion and cervical secretions, suppression of lactation when given immediately postpartum, cholestatic jaundice, migraine, rash (allergic), rise in blood pressure in susceptible individuals, mental depression. Although the following side effects have been reported in users of oral contraceptives, no cause and effect relationship has been established: anovulation posttreatment, premenstrual-like syndrome, changes in libido, changes in appetite, cystitis-like syndrome, headache, nervousness, dizziness, fatigue, backache, hirsutism, loss of scalp hair, erythema multiforme, erythema nodosum, hemorrhagic eruption, and itching. The following occurrences have been observed in users of oral contraceptives (a cause and effect relationship has neither been established nor disproved): thrombophlebitis, pulmonary embolism, neuroocular lesions.

The following laboratory tests may be altered by the use of oral contraceptives: increased sulfobromophthalein and other hepatic function tests, coagulation tests (increase in prothrombin, factors VII, VIII, IX and X), thyroid function (increase in PBI and butanol extractable protein-bound iodine and decrease in T^3 values), metyrapone test, pregnanediol determination.

norethindrone — an original steroid from
SYNTEX 
 LABORATORIES INC., PALO ALTO, CALIF.

Here's why Norinyl-1 makes medical sense.

The effectiveness of Norinyl-1 as a low-dose oral contraceptive may be explained by its possible multiple action. In addition to its primary action of suppression of ovulation, Norinyl-1 may offer additional protective mechanisms... (1) creation of a cervical mucus that may be hostile to sperm penetration, and (2) development of an endometrium that may be out of phase with nidation.

These effects are illustrated below.

Untreated Patient

Cervical mucus at midcycle is usually thin and watery, with Spinnbarkeit (stretchability) of 15 to 20 cm.

Spermatozoa appear healthy, active, freemoving.

Endometrium of untreated patient is receptive to the fertilized ovum during secretory phase.

Norinyl-1 Patient

Cervical mucus at midcycle is scanty, viscous—with Spinnbarkeit of 1 cm. or less.

Immobile spermatozoa as they appear in cervical mucus taken from patient treated with Norinyl-1.

Norethindrone in Norinyl-1 accelerates secretory phase, suppresses glandular and vascular development.

Norinyl-1[®]
(norethindrone 1mg. ± mestranol 0.05mg.) tablets

- new low dose of time-proved ingredients
- established norethindrone/mestranol ratio
- lower patient cost

An uncommon steroid for common inflammatory dermatoses

In everyday topical steroid therapy, Synalar produces rapid resolution of inflammation and itching in steroid-responsive dermatoses—and at relatively low cost to the patient.

Advanced molecular design enhances potency

Synalar combines the advantage of earlier corticosteroid compounds with unique structural innovations. As a result, preparations of Synalar 0.01% and Synalar 0.025% have been reported to be more potent topically and significantly more effective than hydro-

cortisone 1.0%. The unique fluocinolone acetonide molecule provides one of the most useful topical corticosteroids for everyday practice.

Impressive clinical results in a wide range of dermatologic problems

The clinical efficacy of Synalar has been extensively documented in the world literature. Commonly encountered diseases such as allergic and contact dermatitis, eczematous and seborrheic dermatitis, and neurodermatitis respond rapidly to Synalar, often

where previous therapy with other topical corticosteroids has failed.

Low patient cost for wider usefulness

With Synalar, a high degree of efficacy does not mean high price. And—a small quantity goes a long way. Thus, your patients can often obtain the “economy” of a hydrocortisone preparation with the proved efficacy of a potent, truly advanced steroid.

Synalar[®]
fluocinolone acetonide

Turn page for contraindications, precautions and side effects.

For everyday topical steroid therapy

Synalar® 0.01%

fluocinolone acetonide

provides economy in two practical dosage forms

For general use, the most economical and widely applicable concentration of Synalar is 0.01% Cream in a water-washable, vanishing cream base. Synalar Solution 0.01% is especially valuable in dermatoses involving moist, intertriginous areas or hairy sites where creams and ointments do not spread or penetrate readily. Synalar Solution is a unique dosage form—clear, nongreasy, cosmetically elegant.

Product Information

Contraindications: Tuberculous, fungal, and most viral lesions of the skin (including herpes simplex, vaccinia, and varicella). Not for ophthalmic use. Contraindicated in individuals with a history of hypersensitivity to any of the components.

Precautions: Synalar preparations are virtually nonsensitizing and nonirritating. However, the solution may produce burning or stinging when applied to denuded or fissured areas. In some patients with dry lesions, the solution may increase dryness, scaling or itching. Where severe local infection or systemic infection exists, the use of systemic antibiotics should be considered, based on susceptibility testing. While topical steroids have not been reported to have an adverse effect on pregnancy, the safety of their use on pregnant females has not absolutely been established. Therefore, they should not be used extensively on pregnant patients, in large amounts, or for

prolonged periods of time. **Side Effects:** Side effects are uncommon with topical corticosteroids. As with all drugs, however, a few patients may react unfavorably to Synalar under certain conditions. In such cases the agent should be discontinued and appropriate measures taken.

Availability: Synalar (fluocinolone acetonide) Cream 0.025%—5, 15 and 60 Gm. tubes and 425 Gm. jars. Cream 0.01%—15, 45 and 60 Gm. tubes and 120 Gm. jars. Solution 0.01%—20 and 60 cc. plastic squeeze bottles. Ointment 0.025%—15 and 60 Gm. tubes. Neo-Synalar® (neomycin sulfate 0.5% [0.35% neomycin base], fluocinolone acetonide 0.025%) Cream—5, 15 and 60 Gm. tubes.

Tumor Conference

Multiple Primary Carcinoma of the Gastrointestinal Tract*

THE SYNCHRONOUS appearance of two primary carcinomas in one patient was first reported in the German literature in 1880 by Czerny¹ and in the English literature in 1888 by Fenger.² Since that time many other reports have appeared in the literature citing cases of multiple primary carcinomas, and several collective series have been reported over the years.^{3,7,8}

From many clinicians and from reading the literature one gains the impression that the incidence of multiple primary carcinomas in a given patient with cancer may be greater than that expected in the general population on the basis of probability alone.

The following case report is presented as an example of a patient who was found to have three simultaneous primary malignant neoplasms of the gastrointestinal tract. The purpose of this case report is to summarize our current thinking on the significance of such a finding.

Case Report

A 64-year-old woman was admitted to the University of Minnesota Hospitals on February 14, 1967, for treatment of a gastric carcinoma. She had been in good health up to the summer of 1966 when she first experienced symptoms consisting primarily of a feeling of abdominal fullness and epigastric pain. She had no history of hematemesis, alteration in bowel habits, melena, or any other symptoms relative to her gastrointestinal tract.

Physical Findings

Physical examination revealed a thin woman who appeared to be in reasonably good general health, and except for a slight elevation of the systolic blood pressure there was no evidence of cardiovascular or respiratory disease. In the abdomen a 4 x 4-cm. ill-defined, firm epigastric mass could be palpated.

Laboratory Studies

Laboratory values revealed an Hgb. of 14.0 Gm., BUN 19 mgm. %, corrected creatinine clearance of 92 L/24 hours, fasting blood sugar of 61 mgm. %, bromsulphthalein of 7% retention at 45 minutes and an alkaline phosphatase of 11 mgm. %. The electrocardiogram was within normal limits.

*Supported by USPHS Grant #CA-08832-01.

Radiological examination of the chest showed no active pulmonary disease. Examination of the upper gastrointestinal tract revealed a gastric lesion extending along the greater and lesser curvature with obvious fixation and rigidity of the gastric wall (Figure 1).

Fig. 1 — Roentgenograph of stomach demonstrating rigidity of wall with lesion involving the body, antrum and pylorus.

Operative Findings

On February 21, 1967, the patient's abdomen was explored through a midline incision. An obvious gastric carcinoma involved the entire stomach except for the distal one inch of antrum and extended almost to the gastroesophageal junction. Along the lesser curvature several nodes appeared to be involved with tumor; however, no spread to the liver or the peritoneal surfaces was observed. The tumor appeared to be amenable to resection for cure.

Prior to resecting the stomach, exploration of the abdomen revealed a napkin-ring type lesion in the ascending colon near the cecum and a second palpable mass circumferentially involving the sigmoid colon. Both of these colonic lesions were felt to be primary carcinomas. No evidence of spread within the pelvis or to local or regional nodes was discovered on careful palpation.

Procedure

A right colectomy with reconstruction of gastrointestinal continuity by an ileotrans-

verse colostomy was done. Similarly, the sigmoid lesion was resected and a descending colostomy performed, using a single layer end-to-end anastomosis.

A total gastrectomy, splenectomy, omentectomy and a nodal dissection were performed, removing the nodes around the hepatic artery, the retropyloric lymph nodes, and the supra-pancreatic lymph nodes, en bloc. The duodenal stump was oversewn. Gastrointestinal continuity was restored by a loop esophagojejunostomy with a distal entero-enterostomy. The abdomen was closed in layers, using wire sutures to approximate the fascia.

The patient tolerated the procedure very well and left the operating room in good condition.

Pathologic Findings

The Ascending Colon Lesion

The ascending colon lesion was a 2½-cm. annular fungating tumor mass located 6 cm. from the ileocecal valve (Figure 2). Histologically it was an adenocarcinoma arising from the surface epithelium and invading deeply into the muscularis externa. Sections of ten small lymph nodes taken from the attached mesentery and connective tissue showed no evidence of tumor.

Fig. 2 — Fungating adenocarcinoma found in the ascending colon, 7 cm. from ileocecal valve.

The Sigmoid Colon Lesion

The resected sigmoid colon contained a 4-cm. annular ulcerated tumor (Figure 3). Three polyps up to 1 cm. in diameter were noted to be in close proximity to the tumor. Sections showed an adenocarcinoma arising from the surface epithelium and extending deeply to the external edge of the muscularis externa. The tumor appeared to be slightly more active and anaplastic than the other colonic lesion. Sections of the polypoid lesions adjacent to the carcinoma revealed adenomatous polyps. There was no evidence of tumor in 19 lymph nodes taken from the mesentery of the resected specimen.

Fig. 3 — Annular carcinoma of the sigmoid colon with three adjacent adenomatous polyps in close proximity.

The Stomach Lesion

The resected stomach measured 27 cm. along the greater curvature and 16 cm. on the lesser, and included 0.5 cm. of duodenum and 1.5 cm. of esophagus (Figure 4). The stomach was thick-walled with a pebbled mucosa, al-

most devoid of mucosal folds. In the anterior wall a shallow 1.5 cm.-ulceration was found in the mucosa. Grossly the tumor seemed to involve almost the entire stomach. It appeared to extend to about 3.5 cm. from the pylorus. Proximally, no gross tumor was seen within 4 cm. of the gastroesophageal junction.

Fig. 4 — Resected stomach with tumor clearly seen on the cut edges with loss of normal rugal pattern.

Histologically the tumor was a diffuse infiltrating adenocarcinoma arising from the surface epithelium and extending all the way through the muscularis externa to the serosal surface. The lines of resection were free of tumor. Sections taken from ten lymph nodes from the gastrohepatic ligament showed five involved with metastatic tumor. The spleen, including six nodes from the splenic pedicle, and the adjacent omentum showed no evidence of tumor.

Postoperative Course

The patient had a benign postoperative course. The wound healed per primum, and she was discharged from the hospital approximately three

weeks after surgery, on March 10, 1967. At the time of her most recent outpatient visit on August 10, 1967, she was found to be essentially asymptomatic, except for a mild diarrhea which is gradually improving. Her appetite is excellent and she is able to maintain her weight, eating four to six meals daily. There is no discomfort after eating and no evidence of bile regurgitation.

Discussion

Since the early reports of multiple primary malignancies, opinions as to the significance of this phenomenon have varied. Basically, three views have been advanced:

Immunity

A prior cancer confers some immunity to subsequent cancer development, and these patients have a lower incidence of new primary carcinomas than the general population.

The theory of active immunization against a malignant tumor was initially proposed by Michaelis in 1907 on the basis of animal experimentation with transplanted tumors.⁴ In 1942 Schmidt reported a series of 3,700 consecutive autopsies with an incidence of multiple primary malignant tumors of only 0.27%.⁵ On the basis of the relative rarity of multiple primary malignant tumors, Schmidt speculated that the possibility of immunity, against the development of a second malignancy in a patient, indeed existed. In another study by Warren and Ehrenreich in 1944, a series of 2,829 autopsies was reported from patients who died from a malignant neoplasm.⁶ They observed an incidence of multiple primary carcinomas of 6.8 per cent and concluded that cases of multiple malignant growths occur more frequently than the expected incidence based on chance alone. They attributed this greater frequency, which they calculated as eleven-fold, to susceptibility or predisposition to cancer in some persons or groups of persons. The major difference in these two reports dealing with large numbers of autopsies naturally resides in the selection of the material under review.

Predisposition

A cancer manifests itself in a group of patients on the basis of some factor or predisposition making them susceptible to the development of cancer, and this group will have a higher than expected incidence of a second or even a third malignancy.

If one is dealing with a group of individuals who are exposed for many years to the influence of carcinogens capable of producing carcinomas in various sites, this particular group undoubtedly will show a higher incidence of those tumors related to the carcinogen. One might expect that if one were to compare the incidence of a second primary cancer in a large group of smokers who have been successfully treated for a carcinoma of the colon, for instance, the chance for subsequent development of a carcinoma of the lung or the oral cavity would be much higher than in a group of non-smokers who had been cured from a similar carcinoma of the colon. A comparable phenomenon of multiple specific histological malignancies is seen in individuals who have been exposed to ionizing radiation. The incidence of carcinoma of the skin and of leukemia is found to be higher in radiologists than in the gen-

eral population of physicians, particularly in the early years before the carcinogenic potential of ionizing radiation was recognized.

Statistical Chance

Multiplicity of primary carcinomas are chance occurrences. Statistical evidence that multiple primary carcinomas are chance occurrences has recently been presented by Spratt and Hoag.⁷ In a group of 4,300 patients seen at the Ellis Fischell State Cancer Hospital from 1940 through 1961 there were 1,130 with colorectal cancer, 710 with carcinoma of the breast, 1,835 with cancer of the cervix, 167 with chronic leukemia and 1,000 without any malignancy at the time of the initial evaluation.

After following these two groups for five years or more, Spratt and Hoag concluded: "The incidence for the development of cancer in the control group and the development of additional cancers after being afflicted with colorectal cancer, mammary cancer, cervical cancer, chronic leukemia, or lymphoma are no greater per man-year of risk. After cervical cancer the number of cancers per man-year of risk and follow-up was significantly less than that in the control group of women of the same median age. Neither the site of a previous cancer nor the absence of a previous cancer influenced site distribution of new cancers." Using data available in the form of life expectancy tables and recognized disease frequency indices, Spratt and Hoag tabulated the probability of a hypothetical population developing carcinomas. Assuming a population of 100,000, all of them living and surviving to age 90, with none succumbing to their first or subsequent cancers, approximately 51% would develop one malignancy, 17% two malignancies, and approximately 6% would have had the time and propensity to develop three malignancies on the basis of probability alone.

Comments

The multiplicity of carcinomas in the colon and rectum has received particular attention in several excellent articles. In 1958 Grinnell reported an incidence of multiple primary carcinoma of the colon and rectum of 5.8% in 1,083 patients seen at the Presbyterian Hospital in New York City between 1916 and 1952.⁸ Diamonte and Bacon have recently reported their experience with synchronous and non-synchronous primary multiple malignancies of the colon and rectum.³ Of 2,508 patients seen with a carcinoma of the colon, 230 patients, or 9.2%, had more than one primary malignancy. One-hundred thirty-four, or 5.2% of the total group of 2,508, had an additional primary carcinoma of the colon. Of these, 80, or 59.1%, were synchronous lesions found at the time of initial evaluation. Of the total group of 230 patients who had multiple primary carcinomas, three had their second primary cancer within the stomach.

The frequency of multiple carcinomas of the colon and rectum is of importance since these tumors are relatively slow-growing lesions and may go undiscovered for long periods of time. Because of the long period of asymptomatic growth, the opportunity to develop a second tumor during this time is greater than in more rapidly growing tumors such as carcinoma of the lung or stomach. This is probably the reason for the higher frequency of multiple synchronous carcinomas in the colon.

In Fenger's initial report in 1888 he described a patient who preoperatively

was diagnosed as having an obstructing carcinoma of the ascending colon.² The patient was operated upon and an ileotransverse colostomy performed. However, the colonic obstruction was unrelenting and the patient died ten days after the surgical procedure. At post-mortem examination he was found to have a second carcinoma completely obstructing the splenic flexure. From this first case recorded in the English literature and from the many cases of multiple carcinomas of the colon and rectum accumulated through the years, it is apparent that three important steps must be taken in treating the patient with a carcinoma. These are:

1. Thorough preoperative evaluation.
2. Thorough intra-operative examination of the areas exposed at the time of surgery.
3. Careful and continuous follow-up, not only to check for any possible recurrence of the initial tumor, but also to reveal the development of additional neoplasms.

Conclusion

From the brief discussion it is evident that our present state of knowledge does not permit us to draw firm conclusions regarding the influence one carcinoma has upon the development of subsequent carcinomas. To a clinician the significance of multiple malignancies is quite clear. The patient with a carcinoma may already have or later develop a second or even a third malignancy.

On Cosmic Purpose

Is there not something a trifle absurd in the spectacle of human beings holding a mirror before themselves, and thinking what they behold so excellent as to prove that a Cosmic Purpose must have been aiming at it all along? Why, in any case, this glorification of Man? How about lions and tigers? They destroy fewer animal or human lives than we do, and they are much more beautiful than we are. How about ants? They manage the Corporate State much better than any Fascist. Would not a world of nightingales and larks and deer be better than our human world of cruelty and injustice and war? The believers in Cosmic Purpose make much of our supposed intelligence, but their writings make one doubt it. If I were granted omnipotence, and millions of years to experiment in, I should not think Man much to boast of as the final result of all my efforts.*

after surgery

B and C vitamins are therapy: Therapeutic amounts of B and C in stress formula vitamins often are vital during periods of physiologic stress. STRESSCAPS capsules, designed to meet increased metabolic demands, aid in achieving a more comfortable convalescence, a more rapid recovery. After surgery, as in many stress conditions, STRESSCAPS vitamins are therapy.

Stresscaps[®]

Stress Formula Vitamins Lederle

Each capsule contains:

Vitamin B ₁ (Thiamine Mononitrate)	10 mg
Vitamin B ₂ (Riboflavin)	10 mg
Vitamin B ₆ (Pyridoxine HCl)	2 mg
Vitamin B ₁₂ Crystalline	4 mcgm
Vitamin C (Ascorbic Acid)	300 mg
Niacinamide	100 mg
Calcium Pantothenate	20 mg
Recommended intake: Adults, 1 capsule daily, for the treatment of vitamin deficiencies. Supplied in decorative "reminder" jars of 30 and 100; bottles of 500.

When the agitated geriatric disrupts the home...

His teen-age
granddaughter
won't invite
friends
home
because
of his
outbursts.

for moderate to severe anxiety

Mellaril[®]
(thioridazine)
25 mg. t.i.d.

**His slovenly room
and habits create
more tension.**

**His disturbances at
the table make every
meal a nightmare.**

**His daughter
can't please him.
There is "just no
living with him."**

See following page for prescribing information.

When the agitated geriatric disrupts the home...

Anxiety that seriously interferes with the individual's performance at work, at home, or in the community may be regarded as moderate to severe in degree.

Mellaril often recommends itself to the treatment of moderate to severe anxiety because it

- helps control the most frequent symptoms: marked tension, agitation, apprehension, restlessness, hypermotility
- often alleviates anxiety-induced somatic complaints
- frequently helps strengthen emotional resources
- helps the patient maintain realistic contact with environment, closer harmony with family

Thus, when you consider the anxiety moderate to severe... consider Mellaril.

Contraindications: Severely depressed or comatose states from any cause, and in association with or following MAO inhibitors; severe hypertensive or hypotensive heart disease.

Precautions: Hypersensitivity reactions (e.g., leukopenia, agranulocytosis) and convulsive seizures are infrequent. Pigmentary retinopathy has been observed where doses in excess of those recommended were used for long periods of time. May potentiate central nervous system depressants, atropine, and phosphorus insecticides. Where complete mental alertness is required, administer the drug cautiously and increase dosage gradually. In addition, orthostatic hypotension (especially in female patients) has been observed. Epinephrine should be avoided in treatment of drug-induced hypotension.

Side Effects: Pseudoparkinsonism and other extrapyramidal disorders are infrequent; drowsiness, especially in high doses early in treatment, may occur; nocturnal confusion, dryness of the mouth, nasal stuffiness, headache, peripheral edema, lactation, galactorrhea, and inhibition of ejaculation are noted on occasion; photosensitivity and other allergic skin reactions may occur but are extremely rare.

Before prescribing, see package insert for full product information.

Clinical Path Conference

Valvular Heart Disease and Cardiac Arrhythmia

Dr. Stephen C. Weisberg :*

A sixty-five-year-old male was hospitalized because of an episode of unconsciousness. Three years prior to admission, he had noted syncope. Both episodes occurred after the ingestion of large amounts of beer. Dyspnea after climbing three flights of stairs and an isolated episode of undocumented tachycardia were the only other complaints elicited. Review of systems was non-contributory. A digitalis preparation daily was the only medicine. The blood pressure was 150/100, the pulse 80 and regular. Examination of the head and neck was normal. Wheezes were audible throughout the lung fields. A grade III/VI harsh systolic murmur was audible over the aortic area and radiated into the neck and to the apex. The murmur obscured the heart sounds. No diastolic murmur was heard. The remainder of the examination was normal except for a liver edge palpable 4 cm. below the right costal margin and obesity.

The hemoglobin, wbc. and differential, BUN, urinalysis and serum electrolytes were normal. Cardiac fluoroscopy showed a left ventricular configuration but normal heart size. Calcification in the aortic valve and questionably in the mitral valve was also noted. Electrocardiogram showed a left ventricular strain pattern.

The patient was treated with digitalis and a 1,500 calorie diet, and told to avoid beer.

Fifteen months previously he had been hospitalized for the first time because of exertional and paroxysmal nocturnal dyspnea, two-pillow orthopnea and ankle swelling. These symptoms had been present for one month. The blood pressure was 140/95, the pulse 128 and regular. Examination was normal except for bilateral basilar rales, the previous murmur, 3+ pitting ankle edema, distended neck veins and obesity.

Laboratory evaluation was unchanged. Chest x-ray was compatible with congestive heart failure. Electrocardiogram showed a left ventricular strain pattern.

Bed rest, digitalis and diuretics resulted in a 25-pound loss of weight over seven days, decrease in heart size and symptomatic improvement. These medications were continued on dismissal.

Seven months previously he had been hospitalized because of chest pain. Angina pectoris occurring over a five-year period was described at this time. The substernal chest pain responsible for this hospitalization had lasted 30 minutes. The blood pressure was 110/80, the pulse 140 and regular. Examination showed bilateral basilar rales, the previous murmur, a liver 3 finger-breadths below the costal margin and obesity. Laboratory studies including serial serum glutamic oxaloacetic transaminase were normal. The electrocardiogram was unchanged except for a first-degree heart block and digitalis effect. The patient was dismissed on the fourth hospital day.

The third and final hospitalization was necessitated by an episode of unconsciousness. This episode was preceded by nausea and sweating and was evidently brief. Chest pain was denied. Electrocardiogram on admission showed a supraventricular tachycardia. The blood pressure was 140/80, the pulse 130 and respirations 24. Bilateral basilar rales were again audible. Examination of the heart was unchanged. No edema was noted. The electrocardiogram was reinterpreted as showing a nodal rhythm with atrioventricular dissociation. Chest x-ray was unchanged. Treatment consisted of dilantin 250 mg., seconal 100 mg., Aramine 3 mg. and potassium chloride 40 mEq. in a slow intravenous drip. Two hours later, electrocardiogram showed atrial tachycardia with varying block. Vital signs were stable. Fourteen hours later the patient was found dead.

*Chief Internal Medical Resident, Hennepin County General Hospital.

Dr. Weisberg:

The significant historical features of this patient's illness include: angina pectoris of five years' duration, episodes of syncope, exertional dyspnea and tachycardia. Physical findings include a heart murmur characteristic of aortic stenosis, generalized wheezes and an enlarged liver. Cardiac fluoroscopy and electrocardiography help confirm my clinical impression of aortic valvular disease. The findings on the final hospitalization indicate cardiac failure with associated rhythm disturbances.

Dr. Shih Tsai:*

Review of the films shows concentric hypertrophy of the left ventricle progressing over the period of time the patient was seen to left ventricular enlargement and pulmonary congestion. The aortic valve is calcified. No evidence of post-stenotic dilatation of the aorta is present.

Dr. Weisberg:

I believe the primary disease state to be aortic stenosis. Classification of this valvular disorder is best accomplished by defining the etiology and the location of the stenosis. Etiology may be subdivided into: congenital, bicuspid, senile calcification and rheumatic.

Congenital

The congenital type most often occurs in those patients with a congenital unicuspid valve.

Bicuspid

The bicuspid type may be congenital or acquired. The congenital form will most often lead to calcification of the valve. The acquired form is frequently rheumatic in origin, with fusion of two leaflets, and subsequent calcification. Differentiation of the acquired from the congenital form is often difficult except in rheumatic, when other valves may be involved.

Senile Calcification

The third grouping, that of senile calcification, is often seen. In this form, the base of the valve rather than the edges are calcified, as in rheumatic disease.

Rheumatic

Our fourth type is the rheumatic, where fusion occurs at the edges, without calcification of the valve.

Aortic stenosis in adults is most often calcific and valvular in location. Beyond the age of fifty rheumatic or arteriosclerotic is most common, but congenital bicuspid must also be considered. The calcification in this latter group is usually present by age thirty. Many or most of the patients with calcific aortic stenosis have these changes secondary to wear and tear on the valve, or to an aging or degenerative process. This group will thus have a murmur which will appear after age forty or fifty, as opposed to those with a rheumatic or congenital bicuspid valve in which the murmur will appear at an earlier age. Regardless of the etiology, calcification of the aortic valve occurs with increasing duration of the disease and thus with the age of the patient.

*Chief, Department of Radiology, Hennepin County General Hospital.

History

The history first elicited was that of angina, and we will assume this pain was truly angina and exclude chest pain arising from pulmonary infarction, spontaneous pneumothoraces, pericarditis, dissecting aortic aneurysm or esophageal in origin. These problems would not have appeared over a five-year period or resulted in such a progressive clinical syndrome.

Angina

Angina is a very common symptom and was present five years prior to the patient's demise. Angina is noted in over 20 per cent of patients with aortic stenosis and the incidence increases with age. It is due to functional coronary insufficiency, when the increased demands of the hypertrophic left ventricular myocardium may not be met by the coronary circulation which is perfused at reduced pressure.

Syncope

Syncope is also a common manifestation of aortic stenosis and was noted three years prior to the patient's death. Syncope may be due to a sudden transient cerebral anemia or anoxia caused by an insufficient aortic output. The pathophysiologic disturbance in aortic stenosis is that of left ventricular hypertension not necessarily associated with arterial hypertension, which leads to left ventricular hypertrophy. A tremendously elevated left intraventricular pressure maintains a normal aortic and thus a normal cerebral circulation. However, this exists only with usual restricted activity. A small reserve exists; so with stress the heart cannot compensate for an elevation of pressure and thus a rapid response for increased requirements cannot be met.

Cardiac Asthma

Today, the term "cardiac asthma" is often restricted to those patients, as noted here, in whom wheezes resulting from pulmonary congestion are audible. The combination of an enlarged heart, distended neck veins, hepatic enlargement and peripheral edema indicate right heart failure.

A systolic murmur had always been present in the patient's evaluations and is of extreme importance. Occasionally, a mitral holosystolic murmur due to mitral regurgitation or to ruptured chordae tendinae may radiate to the aortic area and the neck and thus simulate a murmur of aortic stenosis. However, this murmur is holosystolic rather than the diamond-shaped ejection murmur of aortic stenosis. In mitral insufficiency I would expect left atrial dilatation and hypertrophy, which are not apparent in x-rays of this patient, and subsequent left ventricular dilatation and hypertrophy, again not seen. In mitral insufficiency I would expect P wave abnormalities in the electrocardiogram, and this also is not noted in this case.

Aortic Stenosis

The characteristic murmur of aortic stenosis is an ejection-type systolic murmur which is loud, harsh, and of low frequency, with a diamond-shaped crescendo-decrescendo character. It is separated from the first and second heart sounds by a short gap. It is heard at the base and most often will radiate to the neck and apex. Associated findings are a forceful apical impulse,

a systolic thrill at the base, an early systolic ejection click along the left sternal border, an atrial gallop often heard in the apical region, and a slowly rising anacrotic* type of pulse with a narrow pulse pressure.

A diastolic murmur was never noted upon examination. Although this murmur might have been masked, I do not believe it was ever present, for I do not believe aortic insufficiency existed. In aortic insufficiency, left ventricular dilatation always accompanies hypertrophy from the inception; however, in this patient concentric enlargement preceded dilatation.

Sudden death is a common occurrence in patients with aortic stenosis, and most often occurs in those patients in whom syncope and angina have previously occurred. The commonest cause of sudden death is chronic myocardial ischemia with resultant heart failure predisposing to serious arrhythmias. Coronary artery occlusion also occurs in the older age groups. Conduction disturbances are common in patients with aortic stenosis. This may be directly related to extension of calcification from the aortic valve into the region of the node or septum or to progressive cardiac failure.

The electrocardiogram is helpful, but initially may be entirely normal with rapid progression to left axis deviation, left ventricular strain and then hypertrophy.

Radiologic Findings

The radiologic findings in aortic stenosis are often characteristic. In uncomplicated cases in which the heart is well compensated, the overall size of the cardiac silhouette may appear normal when there is concentric hypertrophy, as in this case. The left ventricle does not dilate until late in the course, and then with associated failure. Calcification of the aortic valve is, of course, most essential to the diagnosis. Post-stenotic dilatation, not reported in this case, is found in the proximal portion of the ascending aorta in approximately 50 per cent of cases.

Atrioventricular Dissociation

We are told this patient had a pulse of 130 and an electrocardiogram showing a nodal rhythm with atrioventricular dissociation. If the atrioventricular node activates the ventricles, and the atria are activated by the sino-atrial node, the rhythm is termed atrioventricular dissociation. In this rhythm disturbance the ventricular rate is usually less than 60. Since the pulse was 130, I will assume the rhythm disturbance in the terminal stage was that of interference dissociation. Here the atria and ventricles are controlled by independent pacemakers in the presence of retrograde ventricular-atrial block and intact capacity for adequate antegrade conduction. If the ventricles are regulated by an idioventricular focus, the rate is usually less than 150. Most often this rhythm disturbance is digitalis-induced and is often accompanied by, or precipitated by, an acute myocardial infarction or cerebral vascular accident.

Drug Control of Disease

The treatment consists of removing the causative drug or attempted control of the underlying disease state.

Digitalis

Digitalis, while impairing the conduction of impulses from the atria to

*See Test Your Word Score Page 1823.

the ventricles, partially by vagal stimulation, will most often impair conduction in excess dosage by direct action on the conductive tissues. The treatment for such digitalis-induced and/or similar arrhythmias is not potassium, as was given in this case, because potassium also impairs atrioventricular conduction and will potentiate the degree of block. The irritative effect of digitalis must be considered in a different light from the depressive effect, and the treatment certainly differs.

Aramine

Aramine was also given to the patient and was inappropriate treatment. By raising the blood pressure Aramine stimulates the carotid sinus and aortic receptors with consequent vagal stimulation.

Dilantin

Dilantin was also administered, and this drug, like potassium, may induce further depression and block, and should not have been used. Dilantin may be used to combat the irritative effects of digitalis intoxication. Recent evidence indicates that it may enhance atrioventricular conduction in digitalis-induced atrioventricular block and warrants further study.¹

Treatment

The medical treatment for aortic stenosis is essentially symptomatic. The avoidance of physical activity which surpasses the ability of the patient is indicated. Surgical treatment is indicated for patients with syncope, angina and/or left heart failure and should be that of a prosthetic valve. The surgical mortality today is probably less than 15 per cent. After their first attack patients with progressive cardiac failure have usually less than one year to live without surgery.

Final Diagnosis

I believe the final diagnosis is that of calcific aortic stenosis. I would think we will probably find evidence of a bicuspid valve in this individual. I believe death resulted from progressive cardiac failure and improper treatment of a rhythm disturbance that might have been treated with ethylenediamine-tetraacetic acid. The patient should have been considered for a prosthetic valve after his first hospital admission.

Dr. A. M. Richards:*

I feel it is important in a case of this type to also consider other forms of obstruction such as the subvalvular and supra-ventricular aortic stenoses. I think cardiac catheterization would have been of value in this individual to further define his exact lesion and to rule out the possibility of other existing lesions. However, I do not think that this patient, because of his age, would be a suitable candidate for surgery.

Pathologic Findings

Dr. John T. Crosson:**

At the time of autopsy there was minimal evidence of peripheral edema and no definite cyanosis. On opening the body there was no pleural fluid, and the significant pathology was confined to the heart and lungs.

*Assistant Chief, Internal Medicine, Hennepin County General Hospital.

**Resident in Pathology, Hennepin County General Hospital.

The Heart

The heart was quite enlarged, weighing 700 grams. The left ventricular wall measured 2.5 cm. in width, which is significantly thickened, the normal being about 1.5 cm. The right ventricular wall measured only 0.4 cm., which is within normal limits. The mitral valve, the tricuspid valve, and the pulmonary valves were all normal. The aortic valve was the site of major pathology. It was a bicuspid valve. Both cusps were markedly calcified, the majority of the calcification being at the free edge of the cusp, also extending down along the cusp and even in one place up along the aortic wall as well. However, in this area the calcification did not obstruct the coronary ostia. There was continuity between the right and left cusps, and an abortive raphe, considered to be congenital, was in the mid portion of the right and left cusp where a commissure would have been had this valve developed normally. Figure 1 is a picture of the heart at the time of autopsy, exposing the two aortic cusps and showing the degree of calcification. The coronary ostia appear patent. The left ventricular thickening is also evident. There may be a small jet lesion on the endocardial surface of the left ventricle, suggesting some degree of aortic insufficiency. The coronary arteries were examined and interestingly enough appeared perfectly normal. There were no atherosclerotic changes throughout their distribution, nor was there evidence of any calcific emboli into the coronary arteries.

Figure 1

Figure 2

The heart showed evidence both grossly and microscopically of patchy areas of fibrosis but no large unequivocal areas of recent or old infarction. There was evidence of some cardiac muscle hypertrophy on microscopic examination. This heart was also examined by Dr. Edwards who agreed that this probably represented a congenital bicuspid aortic valve which had undergone calcification.

The Lungs

The lungs were markedly congested; the right and left lungs weighed 700 grams and 350 grams respectively. In Figure 2 the severe degree of pulmonary congestion is evident in an external view of the lungs.

The Liver

The liver was slightly enlarged, weighing 2100 grams, but did not show any distinct passive congestion on microscopic examination.

Congenital Bicuspid Valve

Table 1 summarizes some of the factors which would favor the diagnosis of congenital bicuspid valve—some of which apply here and some of which don't. The presence of a congenital raphe, instead of being evidence of previous fusion of two commissures by rheumatic disease, is compatible with a congenital bicuspid valve. The presence of other congenital lesions would support this diagnosis, though no others were detected. The most common anomaly is coarctation of the aorta, but this was clearly absent in this patient. The third factor would be equal cusp sizes. If this was due to rheumatic fusion of the commissures, frequently but not always the cusps would be of unequal size. In this instance, the cusps appear to be relatively equal, suggesting a congenital origin. Finally, the absence of rheumatic disease in the other valves is strongly in support of this being a congenital lesion, although it does not entirely rule out rheumatic involvement.

TABLE I
Factors Favoring Congenital Origin of Bicuspid Valve

A. Congenital Raphe From Valve Leaflet to Aortic Wall
B. Presence of Other Congenital Abnormalities
C. Equal Cusp Sizes
D. Absence of Rheumatic Disease in Other Valves

Rheumatic Valvular Disease

Table 2 summarizes findings that were published by Dr. Paul Dudley White in 1941.² This is a review of some 217 cases of rheumatic valvular disease at the Massachusetts General Hospital and shows the distribution of the valves involved. From his study it is apparent that isolated aortic valve involvement is quite rare. Approximately 70% of patients with rheumatic valvular disease of all sorts will have aortic involvement; however, only 5% of these will have only isolated aortic valve involvement, either aortic stenosis or aortic insufficiency. Dr. Edwards, in theorizing a mechanism for calcification, contrasts the anatomy of the normal tricuspid aortic valve with that of the congenital bicuspid valve. He stresses that in this tricuspid valve the free edges of the aortic valve cusps are longer than the distance between the points of attachment of the cusps on the wall of the aorta. This extra length

to the valve cusp is important in allowing these cusps to open and close without stress. In the congenital bicuspid valve this extra length is not present. The length of the free edge of the cusp in this valve equals the distance between the points of attachment of the cusps on the aortic wall. This allows the aortic valve to open somewhat, but there is some stress and strain put on the valve cusps when opened completely during systole, and the valves then are subject to the trauma of the turbulent blood flow. Sometimes the bicuspid valves will be a little longer than they should be for the distance between the two walls of the aorta. If this is the case, the valves will open normally but not close normally. There will be a prolapse of one or both of the valves with some degree of regurgitation which will then be a source of trauma to the valve. It is Dr. Edward's feeling that this persistent trauma to the collagen bundles in the valve produces a change in the bundles which would be evident if we were fortunate enough to see progressive cases of these diseases. He feels that it is this change which predisposes the valve to the deposition of calcium. He also believes that the same change in the collagen predisposes these valves to the development of subacute endocarditis as well.³

This patient had clinical evidence of myocardial ischemia for some five years prior to his death. However, at the time of autopsy we found no evidence of coronary artery disease. Not infrequently, patients who have aortic stenosis will also have concomitant coronary artery disease which can account for their angina. However, a very significant group of the patients have no coronary disease at all, and this phenomenon of patients with aortic stenosis, angina, and normal coronary arteries has been recognized for quite a few years now. In 1939, Dry and Willius stated that the degree of coronary disease was inversely proportional to the degree of calcific aortic stenosis.⁴ There have been some studies more recently that also support this view. In 1965, Dr. Edwards published a series of cases in which the degree of coronary artery disease for given age groups was compared in patients who had aortic stenosis. From this study he concluded that there was a tendency for lesser degrees of coronary disease to be present in the fifth, sixth and seventh decades in males who have aortic stenosis compared with patients in similar age groups who do not have aortic stenosis.⁵ I think we are seeing an example of this phenomenon in the patient discussed today. Finally, if the coronaries are normal, why do these patients have both clinical and pathological evidence of myocardial ischemia?

Mechanisms

There has been some discussion by Dr. Weisberg of the mechanisms that might be involved. To me the most reasonable mechanism would relate to the muscular hypertrophy. Because of the marked pressure gradient across the aortic valve, the person who is maintaining a normal pressure in the aorta will have a markedly increased intraventricular pressure, and at the time of

systole, there would be a tremendous increase in pressure on the coronary arteries coursing through the myocardium which would undoubtedly tend to decrease the coronary blood flow. Although this pathogenesis would seem reasonable, a study in *CIRCULATION* in 1965 tended to discount this theory. That study concluded that the coronary blood flow per unit of weight of myocardium in patients with aortic stenosis was the same as in normal patients. In addition, coronary blood flow in these same patients following exercise was found to increase to the same degree as it did in normal patients. These patients with aortic stenosis all had angina, and all manifested clinical evidence of myocardial ischemia.⁶ Therefore, I do not think we yet know the cause of the myocardial ischemia, although we do know that it frequently occurs. We can certainly see pathological evidence of it, and there are many patients cited in the literature who have clinical evidence of ischemia. The presence of syncope, as Dr. Weisberg discussed, is a puzzling matter also but probably not as hard to explain as that of the angina. In 1951, Hammarsten was able to find several cases in the literature in addition to some of his own cases where it was fairly well documented that the syncopal attack suffered by patients with aortic stenosis was associated with decreased cardiac output and normal sinus rhythm or with bradycardia. He found a relationship between angina and syncope in his patients, and he also observed that in some patients the syncopal episode was directly preceded by an attack of angina. He concluded that the syncope was due to decreased cardiac output, and, as Dr. Weisberg indicated, probably due to a sudden episode of myocardial ischemia.⁷ I do not think the mechanism of the sudden myocardial ischemia is understood at all. It seems apparent from the literature, however, that patients with aortic stenosis are prone to develop sudden episodes of myocardial ischemia. If we accept this as being true, I think we can explain the sudden death in many of these patients, because we certainly know that episodes of myocardial ischemia can predispose the myocardium to serious and often fatal arrhythmias.

One final possibility that Dr. Weisberg mentioned that I think worth re-emphasizing is that patients with aortic stenosis do have difficulty with the conduction system. They have varying degrees of heart block which in some cases has been shown to be due to extension of the calcification process directly involving the bundle of His. In this particular case we don't have any studies of the bundle of His, and I don't know whether this man's conduction system was intact or not. However, he did have clinical evidence of condition difficulties which were likely progressive. Failure of the ventricular pacemaker with either asystole or ventricular fibrillation was probably the most likely cause of his demise.

Summary

We have a patient who has a five-year history of episodes of syncope and angina, who has definite clinical evidence of calcific aortic stenosis, who was found at autopsy to have a bicuspid congenital calcific aortic stenosis.

Dr. Fred Shapiro:*

I would appreciate Dr. Weisberg's comment on what drugs might be used in an individual in shock with possible evidence of digitalis intoxication.

*Assistant, Internal Medicine, Hennepin County General Hospital.

Dr. Weisberg:

The patient in this case was not in shock, as the protocol indicated the pressure to have been 140/80. As I indicated before in my discussion, whether the arrhythmia this patient manifested was digitalis-induced or not, ethylenediaminetetraacetic acid may have been indicated, for this drug would not have caused a further depression of the heart's conduction pathways. The drugs employed in this case were of a depressive nature on the conduction system. Dr. Richards, you might wish to comment on what drugs you would recommend for a problem of this type.

Dr. Richards:

We really do not have a good treatment for digitalis intoxication of this sort. I have not been impressed with ethylenediaminetetraacetic acid because of its side effects of nausea and vomiting and have thus tended not to use this agent. I think that today with our present coronary care unit facilities the patient should be monitored and arrhythmias treated as they arise.

Dr. Weisberg:

The problem that arises in this case is the presence of atrioventricular interference association and I feel quite strongly the drugs used were inappropriate and caused further depression on the cardiac conduction system. The only drug that would have been available that would not have caused further depression on the conduction system would have been ethylenediaminetetraacetic acid, and thus I think this drug, if any drug was to be used, might be indicated.

Dr. Shapiro:

I wonder if in this case with such a problem as may have been induced by digitalis, the best treatment would have been no treatment at all.

Dr. Weisberg:

I agree that the most conservative approach would be to withdraw the drug which might be precipitating such an arrhythmia. In this case, we of course realize the underlying organic heart disease may have been the major factor in contributing to the arrhythmia, and digitalis may or may not have been an important precipitating effect.

Dr. Thomas Stillman:

I agree with Dr. Weisberg that the irritative and depressive effects of digitalis must be separated and recognized and that their treatment does differ, as he has indicated.

Functions

In illness the physician is a father; in convalescence, a friend; when health is restored, he is a guardian.—Brahmanic saying

Nail Dystrophies

A 25-YEAR-OLD woman sought help for a nail abnormality of five years' duration. Without illness or other apparent cause a groove developed in her thumb nail, extending from the lunula to the free edge. The condition lasted approximately six to 12 months; then the nail would resume a normal pattern of growth. The condition recurred; first one thumb nail then the other would become involved. She was in good health with a past medical history which was noncontributory and there were no occupational or other forms of trauma to account for these changes. A diagnosis of *dystrophia mediana canaliformis* was made (see Figure).

When abnormal and deformed in any way, the nails may be a source of considerable concern to a patient and a cause for frustration on the part of the physician to whom the problem is presented. Nail dystrophies (onycho-dystrophies) are diverse affections which may be secondary to various pathologic states or of unknown cause. The present case illustrates one of the rare dystrophies which apparently have no definite local or systemic cause. Trauma as well as a nervous origin have been implicated. However, the condition is benign and any treatment should be conservative.

Another benign and very common dystrophy is *leukonychia*.* In this affection one or more white puncta or striae occur transverse to the axis of the

*See Test Your Word Score Page 1823.

Figure

nail plate. Rarely is the nail totally involved (leukonychia totalis). The fingernails are most commonly affected. This condition is not symptomatic of systemic disease. Trauma as well as imperfect or faulty cornification have been considered possible causes.

Hypertrophy of the nail is called *onychauxis*, the toe nails being more commonly involved. If the nail becomes claw-like the term *onychogryphosis* is used. These abnormalities occur in aged ill-kept individuals and at times in association with peripheral neuritis, stasic changes, hemiplegia, ichthyosis, tabes, or leprosy. Subungual hyperkeratosis may occur with these dystrophies, as well as with psoriasis, eczema and fungal disease. This latter point is well to keep in mind, for not all thickened nails are due to a mycotic infection.

Separation of the nail from its bed or matrix is another common dystrophy. When the nail separates distally it is termed *onycholysis*, while if the separation occurs proximally the term *onychomadesis* is applied. *Onycholysis* has been attributed to eczema, psoriasis, syphilis, trauma (both mechanical and chemical). *Onychomadesis* has been associated with scarlet fever, alopecia areata, exfoliative dermatitis, trauma and infections around the nail bed. Also hereditary examples of these dystrophies occur.

Of those dystrophies associated with systemic disease, *koilonychia* or "spoon nail" is a good example. This condition has been reported with various anemias, including Plummer-Vinson syndrome, and with thyrotoxicosis, polycythemia vera and trauma. Another example is Beau's lines, which are transverse sulci appearing at the lunula and progressing to the free edge. These were first described by Beau in 1846 as an indication of previous disease or trauma.

This discussion by no means exhausts all the various nail dystrophies but does point out the diverse way this epithelial appendage can respond to known and unknown factors. Treatment is directed toward the underlying disease, if it can be determined; otherwise treatment should be conservative.

Minnesota Medicine Cover Photographs

In order to encourage more physicians to submit color slides for use on the cover of MINNESOTA MEDICINE the competition is being discontinued. The picture editor now invites all physician-photographers to send 35 mm. color slides of suitable subjects for consideration as cover pictures. The format must be horizontal because of printing limitations. Pictures high-lighting Minnesota seasons, places, and activities will have an automatic advantage. No limit as to the number of slides sent will be set, but all slides should be individually identified. All slides will be returned. Physicians whose pictures are used as covers will be recognized in MINNESOTA MEDICINE. We can use many more pictures than we have received in the past.

I can reason down or deny everything, except this perpetual Belly: feed he must and will, and I cannot make him respectable.—Emerson

If there's a broader susceptibility pattern of organisms, we've yet to see it.

DECLOMYCIN has always belonged in the foremost rank of the broad-spectrum, general-purpose antibiotics. Indeed, no antibiotic has yet appeared which controls a wider range of pathogens responsible for the clinical infections seen in the day-to-day practice of busy medical men.

You can depend on DECLOMYCIN. A twice-daily dose of 300 mg is a sensible schedule that will cover the patient *day and night*, without risk of blood concentrations dropping below therapeutic levels. This is because of high serum binding and slow renal clearance.

And there is no need to give higher daily dosage than 300 mg b.i.d., except in venereal diseases and Eaton Agent pneumonia.

DECLOMYCIN[®]
DEMETHYLCHLORTETRACYCLINE

Prescribing information on next page.

Rickettsia

Treponema

If there's a broader susceptibility pattern of organisms, we've yet to see it.

DECLOMYCIN Demethylchlortetracycline should be equally or more effective therapeutically than other tetracyclines when the offending organisms are tetracycline-sensitive.

Contraindication: History of hypersensitivity to demethylchlortetracycline.

Warning—In renal impairment, usual doses may lead to excessive accumulation and liver toxicity. Under such conditions, lower than usual doses are indicated, and, if therapy is prolonged, serum level determinations may be advisable. A photodynamic reaction to natural or artificial sunlight has been observed. Small amounts of drug and short exposure may produce an exaggerated sunburn reaction which may range from erythema to severe skin manifestations. In a smaller proportion, photoallergic reactions have been reported. Patients should avoid direct exposure to sunlight and discontinue drug at the first evidence of skin discomfort. Necessary subsequent courses of treatment with tetracyclines should be carefully observed.

Precautions—Overgrowth of nonsusceptible organisms may occur. Constant observation is essential. If new infections appear, appropriate measures should be taken. In infants, increased intracranial pressure with bulging fontanels has been observed. All signs and symptoms have disappeared rapidly upon cessation of treatment.

Side Effects—Gastrointestinal system—anorexia, nausea, vomiting, diarrhea, stomatitis, glossitis, enterocolitis, pruritus ani. Skin—maculopapular and erythematous rashes. A rare case of exfoliative dermatitis has been reported. Photosensitivity; onycholysis and discoloration of the nails (rare). Kidney—rise in BUN, apparently dose related. Transient increase in urinary output, sometimes accompanied by thirst (rare). Hypersensitivity reactions—urticaria, angioneurotic edema, anaphylaxis. Teeth—dental staining (yellow-brown) in children of mothers given this drug during the latter half of pregnancy, and in children given the drug during the neonatal period, infancy and early childhood. Enamel hypoplasia has been seen in a few children. If adverse reaction or idiosyncrasy occurs discontinue medication and institute appropriate therapy.

Average Adult Daily Dosage: 150 mg q.i.d. or 300 mg b.i.d. Should be given 1 hour before or 2 hours after meals, since absorption is impaired by the concomitant administration of high calcium content drugs, foods and some dairy products. Treatment of streptococcal infections should continue for 10 days, even though symptoms have subsided.

In the treatment of syphilis a dosage schedule of a total of 12 to 18 Gm. given in equally divided doses over a period of 10 to 15 days should be followed. Close follow-up observation of the patient is recommended, including appropriate laboratory tests, since demethylchlortetracycline has not had adequate evaluation in all stages of syphilis. Spinal fluid examination should be included as part of this follow-up.

Acute gonococcal anterior urethritis in males has been treated effectively with a single dose of 600-900 mg. of DECLOMYCIN Demethylchlortetracycline. Individuals unable to tolerate large single doses due to gastrointestinal side effects may be treated with 150 mg. every 6 hours for a minimum of 4 doses or 300 mg. every 12 hours for a minimum of 2 doses. Females should be treated with a dosage of 150 mg. every 6 hours or 300 mg. every 12 hours until a cure is affected. Primary Atypical Pneumonia (Eaton Agent): The average adult daily dosage is 900 mg. in 3 divided doses for six days.

American Cyanamid Company, Pearl River, N.Y.

Grand Rounds

Polycythemia Vera*

OLE JERDE, M.D.
Medical Resident

Etiology

POLYCYTHEMIA VERA is a disease of unknown etiology which is characterized by a pancytosis** of the bone marrow. Various theories including hypoxia of the bone marrow and possible hormonal cause have been postulated; however, it is now considered to be a neoplastic disease.¹ Dameshek² feels that polycythemia vera is one of the myeloproliferative diseases which include chronic granulocytic leukemia, agnogenic** myeloid metaplasia of the spleen, megakaryocytic leukemia, and erythroleukemia. He states that 10 to 20% of patients with polycythemia vera, unless dying early in their disease, will develop anemia with a "leuko-erythroblastic" blood picture and will have myeloid metaplasia of the spleen in addition to myelofibrosis. The myeloid metaplasia with splenomegaly may begin before there is fibrosis in the bone marrow, indicating that this is not a purely compensatory extramedullary hematopoiesis. While these diseases may be independent entities, there are numerous case reports in the literature of transition from one to the other. Wasserman¹ studied 61 cases of myelofibrosis with myeloid metaplasia and found that 58% of these patients had a history suggestive of polycythemia vera. In chronic granulocytic leukemia, especially early in the course of the disease, erythrocytosis and thrombocytosis are commonly present. There are three case reports in the literature in which erythroleukemia followed polycythemia vera.³ These authors speculate that P_{32} therapy may have been a factor. Erythropoietin, a humoral substance produced in the kidneys and possibly other tissues, is important in the genesis of polycythemia secondary

*Presented as a Medical Grand Rounds at Hennepin County General Hospital, Minneapolis, April 18, 1967.

**See Test Your Word Score Page 1823.

to other diseases; however, it does not appear to play a role in polycythemia vera.⁴

Clinical Features and Differential Diagnosis

The onset of polycythemia vera is gradual and the complaints and symptoms may be varied. Patients often complain of headaches, aches and pains throughout the body, visual disturbances, loss of memory, fatigability, and dyspnea on exertion.⁵ Dizziness is quite common and has been reported in over 10% of patients.⁶ In a third of a series of 250 patients the first signs and symptoms were related to hemorrhage or thrombosis, illustrating one of the complications of this disease (Table 1).⁶ Other manifestations include itching, gait disturbances, paresthesias, and gastrointestinal complaints. In Lawrence's series⁵ 19% of the patients had peptic ulcer disease. While the incidence in other series is less than this, ulcer disease is common in polycythemia vera.⁷ The plethoric, ruddy face is quite characteristic of this disease. Hepatomegaly is present in 25⁵ to 50%⁹ and splenomegaly in 75%⁹ of the cases.

*Chievitz, E., and Thiede, T.: *Acta Med Scand* 172:513, 1962.

The differential diagnosis of polycythemia vera includes the following disorders:⁹

Secondary polycythemia
 "Stress" polycythemia
 Erythropoietin polycythemias
 Polycythemia with tumors
 Primary erythrocytosis (See Tables 2 and 3)

"Stress" polycythemia, pseudopolycythemia,¹⁰ or Gaisbock's disease¹¹ can be easily confused with polycythemia vera. The patients have ruddy faces and complaints suggestive of polycythemia vera. They are of stocky build, slightly obese, often hypertensive and frequently rather nervous and anxious-appearing. The venous hematocrit and hemoglobin are elevated; however, the platelet and leukocyte counts are normal. Isotope studies reveal a normal red-cell mass with a decreased plasma volume which accounts for the

elevated hematocrit reading. This is a chronic problem and patients have been followed for ten years with no change in the blood-volume studies, clinical picture, or blood morphology.¹¹ It is important to distinguish this disease from polycythemia vera since phlebotomies are of questionable value and therapy with P₃₂ is contraindicated.^{11,12} The etiology of "stress" polycythemia is unknown.

Secondary polycythemia is due to a low arterial blood oxygen saturation. This occurs in patients with congenital heart disease, severe pulmonary disease, and in people living at high altitudes. It also occurs in the Pickwickian syndrome and in diseases with impaired oxygen transport.⁹ Clinically there should be little difficulty in distinguishing this group from polycythemia vera (Tables 3, 4 and 5).

TABLE 2*

Polycythemia vera
Secondary polycythemia—including Pickwickian syndrome
"Stress" polycythemia
Erythropoietin polycythemias (with normal blood O ₂ saturation):
cerebellar hemangioblastoma
renal cancer
renal adenoma
hydronephrosis
renal cysts
Polycythemia with tumors (erythropoietin not demonstrated):
adrenocortical carcinoma or hyperplasia
ovarian carcinoma
hepatoma
pheochromocytoma
Primary erythrocytosis (of childhood)—benign familial polycythemia

*Berlin: Seminars in Hematology, p. 209, July 1966.

TABLE 3*
Differential Diagnosis of Polycythemia Vera: History and Examination

Polycythemia Vera	Stress Erythrocytosis	Anoxemic Erythrocytosis	Tumor Erythrocytosis
History			
Multiplicity of symptoms	Symptoms of nervous tension	High altitude	History may be lacking or related to tumor
Peptic ulcer (20%)	Peptic ulcer, common	Chronic lung disease Congenital heart disease	
Gout occasionally	Gout occasionally	Extreme obesity (Pickwickian syndrome)	
Severe itching skin after bathing (50% of cases)	No itching of skin after bathing	No itching of skin after bathing	No itching of skin after bathing
Physical Examination			
Plethora of skin and mucous membranes	± Plethora of skin; mucous membranes normal	Cyanosis	No cyanosis, clubbing, heart or lung disease
Distention of retinal veins	Retinal veins normal	Clubbing of fingers ±	Occasional mass in left upper quadrant or in pelvis
Hepatomegaly (50%)	Occ. hepatomegaly Acrocyanosis common		
Splenomegaly (75%)	No splenomegaly	No splenomegaly	No splenomegaly

*Dameshek, W.: Seminars in Hematology, 3:214, 1966.

Another group of patients may present with polycythemia and with study will be found to have benign and malignant conditions accounting for it. Cerebellar hemangioblastomas are a common cause in this group. In a review of the literature Waldmann et al.¹³ found that a polycythemic syndrome was present in 9 to 20% of these tumors. Bone-marrow biopsies, when performed, generally showed erythroid hyperplasia, and red-cell volumes were usually increased. Arterial oxygen studies were generally normal. Fluid removed from the cyst was injected into rats and gave rise to an increase in erythropoiesis as determined by radioactive iron studies. When the tumor is resected, the patient's hemoglobin quickly returns to normal, but rises again with recurrence of the tumor. It would appear that these tumors secrete a substance that gives rise to erythropoiesis.

Various kidney lesions can also produce a polycythemic picture. These include hypernephromas, hydronephrosis, benign adenomas, and renal cysts.^{8,9,14,15} Erythropoietin has been found in most of these lesions with clinical remission of the syndrome postoperatively.

TABLE 4*
Differential Diagnosis of Polycythemia Vera: Blood and Bone Marrow

Polycythemia Vera	Stress Erythrocytosis	Anoxemic Erythrocytosis	Tumor Erythrocytosis
Blood:			
Hgb. ++ (to 20 Gm)	+ (to 17 Gm)	+ to +++	+
RBC +++ (7-12 M)	+ (to 6.5 M)	+ to +++	+
Hct. 60-80%	50-55%	50-80%	50-60%
Retics. + (12-6%)	Normal	Normal or slight +	Normal or slight +
Wbc. + (12-20 ³)	Normal	Normal	Normal or slight +
Platelets ++ (2-10 ⁶)	Normal	Normal	Normal
Polys +	Normal	Normal	Normal or slight +
Bands +	Normal	Normal	Normal or slight +
Occ. myelocyte	No myelocytes		
Occ. nucleated RBC.	No nucleated RBC.		
Bone Marrow:			
Wbc. ++	Erythrocytosis- no pancytosis	Erythrocytosis- no pancytosis	Erythrocytosis- no pancytosis
Wbc. ++	Normal	Normal	Normal
Megas +++			
Sed Rate: 0-1	Normal (10-20)	Normal or low

Hepatomas of the liver,¹⁶ as well as one case of a hamartoma of the liver,¹⁷ have been reported to cause polycythemia. Many of these patients had underlying cirrhosis of the liver. Following removal of the hamartoma the patient's hemoglobin returned to normal and remained there during a one-year follow-up. An erythropoietic-stimulating substance was not demonstrated but was presumed to be present. Berlin⁹ notes other tumors that have also caused polycythemia.

In general, the exact diagnosis of most polycythemic conditions can be made on the basis of history, physical examination, peripheral blood studies and bone marrow examination. Other laboratory procedures to be done include the sedimentation rate, which tends to be very low in polycythemia vera but may also be low in anoxemic conditions, and oxygen saturation studies to delineate the anoxemic group. The red-cell mass study will be normal in "stress" erythrocytosis but is elevated in the other types.⁸ Radioactive iron studies will be normal in "stress" erythrocytosis but is elevated in all conditions in which there is erythroid hyperplasia.¹⁸ The leukocyte alkaline phosphatase is generally markedly elevated in polycythemia vera and appears to be a reliable test for separating polycythemia vera from the other three groups. This substance, however, may be elevated in other blood dyscrasias also.¹⁹

Course and Complications

The natural course of polycythemia vera is not well known since therapy is usually instituted as soon as the diagnosis is made. Most investigators agree with Wasserman and Gilbert²⁰ that the "erythrocytic phase" occurs first and is characterized by proliferation of the erythroid cells as well as other cell lines. Assuming the patient survives this phase of the disease, he may enter the "spent phase," which again may last for years and is characterized by decreased erythroid activity and anemia. Myelofibrosis and myeloid metaplasia may occur in this "spent phase".²⁰

Chievitz and Thiede⁶ reviewed the case records of 250 deaths in patients who had polycythemia vera, one hundred eleven of whom were untreated or treated with venesection alone. Of those untreated approximately 50% died within 18 months. Of those treated by venesection alone, 50% died in about 3½ years. However, of these 111 cases, 36 were alive at the five-year

TABLE 6*
Causes of Death

	No. of Patients

follow-up and 15 at 10 years. In Videbaek's series⁷ of 125 patients who were treated by various means other than P_{32} the average duration of the disease was six years in male patients and nine in female.

Hemorrhage and thrombosis in the untreated patient is the most common cause of death and accounted for 123 deaths in Chievitz and Thiede's series⁶ (Table 6). Sixty-three per cent of the deaths in untreated patients were due to thrombosis, while 52% of those treated by venesection alone died of thrombosis.

Polycythemia vera is unusual in that both hemorrhage and thrombosis are very common. The fibrin network appears to be more friable than usual with "fallout" of red cells, even though the platelet counts are normal or elevated.²¹ These authors also noted a qualitative defect in platelets. Sheehy et al.²² postulated that a triad consisting of (1) excess abnormal platelets, (2) increased red cell mass, and (3) fibrinogenopenia probably accounted for hemorrhage. Wasserman and Gilbert²³ found a defect in the platelet fibrin network. Further studies revealed a defect in 5-hydroxytryptamine in 50% of the patients they studied.

As mentioned previously, peptic ulcer is quite common and occurs in up to 20% of polycythemia vera patients.⁸ This, plus the bleeding problem already present, makes gastrointestinal bleeding a common and serious problem.

Hyperuricemia has been noted in up to 80% of patients with either untreated or "spent" polycythemia vera and myeloid metaplasia.²³ Gout is much less common but occurs in 6²⁴ to 13%.⁶ Other complications include, pathological fractures, pancytopenia, nephrolithiasis, splenic infarcts, and hemolysis.²⁰

Treatment of Polycythemia Vera

Patients may present with erythrocytosis and may be relatively asymptomatic. Gardner²⁵ recommends repeated phlebotomies to reduce the hematocrit to 42%. If the hematocrit can be maintained in this range by no more than six phlebotomies per year, he would not use other therapy. This produces a mild iron deficiency which retards erythropoiesis. Platelet counts should be followed closely, since repeated phlebotomies may stimulate the bone marrow, producing a thrombocytosis.²⁰ Most patients, however, will need myelosuppressive therapy, using either P_{32} or various drugs.

Radioactive phosphorus was first used in the treatment of this disease by Lawrence²⁶ in 1940 and has been widely used since. P_{32} will give good results in most patients. Lawrence⁵ reported a 90% incidence of remissions. Ledlie²⁷ reported satisfactory results with clinical remissions lasting up to 22 months. Szur and Lewis²⁸ reported good to partial responses in 96% of the patients in their series of 169 cases. In 90% or more of patients, P_{32} will produce a clinical remission, with improvement in the patient's symptomatology in addition to improvement in the blood picture. Lawrence⁵ recommended using small doses of P_{32} and reported no serious bone-marrow depression. He preferred using 3 millicuries intravenously, followed by phlebotomies, if necessary, to reduce the red-cell mass with re-evaluation and a similar dose of P_{32} , if necessary, in three months. It occasionally took one to two years to induce a remission; however, the disease was usually under control during this period of time. Generally 3 to 6 millicuries of P_{32} are given initially, the dose tending to be proportional to the severity of the disease. Platelet and white cell counts tend to be easily controlled with this drug; however, phlebotomies may be needed to help control the red cell count. Another

favorable factor with P_{32} is the convenience for the patients. After a remission they need less frequent clinic visits and blood studies compared with patients taking drugs.²⁵ P_{32} effectively controls the disease for many years. Several authors^{5,29,30,31,32} report a median survival of 13 years after therapy.

The main complication of P_{32} centers around the relationship of polycythemia vera and acute leukemia. There are numerous case reports describing the transition of polycythemia vera to acute leukemia. Schwartz and Ehrlich³³ in 1950 reviewed the literature concerning these two diseases and rejected all but 30 case reports. Most of these patients had been treated by X-ray therapy, P_{32} , or both. The authors concluded that when acute leukemia occurred in polycythemia vera patients it was due to irradiation. Halnon and Russell²⁹ in a large series all treated with X-ray therapy or P_{32} found no cases of acute leukemia. Ledlie's series²⁷ in which all were treated with P_{32} reported five of 21 deaths to be due to acute myeloid leukemia. One of his patients had immature white blood cells in the peripheral blood and all had had white blood counts greater than 10,000 before therapy. These patients all developed their leukemia within four years of therapy. Masouredis and Lawrence³² noted that the patients who developed acute leukemia had had higher white blood counts, higher platelet levels and more immature cells in the peripheral smear before treatment. They postulated that the leukemia potential was present before therapy and that P_{32} served to trigger it. In Osgood's series³⁰ the patients treated with P_{32} survived longer than those under other methods of therapy, and he theorized that leukemia might be a natural complication in those patients who survived long enough to get the disease. Modan and Lilienfeld³¹ found an incidence of 11% acute myeloid leukemia in patients treated with P_{32} and less than 1% in the non-irradiated group. Prolonged survival did not seem to be the answer since there was little difference between the irradiated and the non-irradiated group. The onset of leukemia was not related to time but was related to the total dose given. Fifty per cent of patients had the onset of acute leukemia within the first eight to nine years after therapy.

Busulfan, an alkylating agent, is one of the commonly used drugs giving good results. Wald et al.³⁴ reported five patients treated with Busulfan with good clinical results in all. He noted a significant reduction in white blood cell, red blood cell and platelet counts with remissions lasting three to 20 months. Killman and Cronkite³⁵ used Busulfan on 12 patients with good response in all. Platelet and white cell counts were significantly reduced with less reduction in the red-cell mass which could be controlled by an occasional phlebotomy. Louis³⁶ reported 18 patients treated with Busulfan with complete remission in 11 patients and incomplete remission in six others. Patients required close observation since there was a marked variation in the individual dosage.

Pyremethamine, a folic-acid antagonist, has been used in England with good clinical results. Megloblastic anemia was a common side effect but was easily corrected by decreasing the dose or adding folic acid.

Cyclophosphonide and chlorambucil have been used with good clinical responses.²⁰

Perkins et al.³⁷ report a series of 127 patients treated with a variety of drugs and/or venesection with a median survival of 13.6 years. They have not observed any cases of acute leukemia.

Vercyte is a very effective drug in the treatment of polycythemia vera.^{38,39} Red-cell mass, white blood cell and platelet counts are effectively controlled

on low doses. While there may be some cases of bone-marrow depression, these have all been reversible. No cases of leukemia have been reported. Diarrhea may be a problem and one patient was unable to tolerate the drug because of this.³⁹

Case Report

A 74-year-old white male was admitted to Hennepin County General Hospital on December 9, 1966, because of weakness and difficulty in walking for about six weeks. His knees would "buckle" and he would fall. He had been getting worse, and on the day of admission he had fallen and been unable to get up.

The patient had been hospitalized here in April, 1965, following a syncopal attack. Hgb. 21.5 and 23, HCT. 66, wbc. 13,900, platelet count 330,000. He had signed out, however, against medical advice before studies could be completed.

The patient was a well-developed, slightly lethargic, ruddy-faced white male. B.P. 130/70, P. 96, R. 26. EENT-Fundi showed some ruddiness with mild venous congestion but no pulp edema. Heart normal. Lungs normal. Abdomen-liver edge two finger-breadths below right costal margin. Spleen not palpable. Extremities-moderate cyanosis of toes and fingers. Neurological-trunkal ataxia with dysnergia and dysmetria of lower extremities.

Hgb. 24.4 gm.%, HCT. 71.5%, wbc. 13,500/mm³, 90% neut., 6% lymph., 1% mono., 3% eos., RBC 7.07 million/mm³, platelet estimate 258,000/mm³, reticulocyte count 0.9%, E.S.K. 0 mm/hr. uric acid 9.0 mg.%, chest X-ray normal, electrocardiogram left axis deviation.

A neurological consultation was obtained and the impression was that the neurological picture was due to ischemia of the brain stem. The patient was treated with phlebotomies at about 400 cc. daily. On December 14, 1966: Hgb. 23.4, HCT. 68, wbc. 14,000, platelet count 318,000, blood vol. 7,100 cc., pH. 7.50, PO₂ 72 mm. Hg.-95.9% saturation, PCO₂-29.

The patient gradually became more lethargic and somnolent and developed paresis of the left upper arm and both lower legs. IVP showed some fibrolipomatosis but was otherwise normal. Brain scan was non-diagnostic. Electrocardiogram was interpreted as mildly abnormal with paralysis of left arm and extreme paresis of both lower legs. He then developed thrombophlebitis of the right lower leg extending to the groin and was started on heparin. On January 3, 1967: Hgb. 16.9, platelet count 466,000. Shortly after starting heparin the patient's thrombophlebitis improved along with slow but steady improvement in his neurological picture. A bone marrow, done on January 29, 1967, showed hypercellularity and a slight decrease in iron stones and was compatible with polycythemia vera. The patient was given 5 millicuries of P₃₂ IV and discharged on dicumarol to the care of his private physician.

"Man's best friend" in wintertime diarrheas

In winter "flu" and viral gastroenteritis, Donnagel (4 oz. size!) can bring aid and comfort to sufferers from both diarrhea and its discomforts because it contains kaolin and pectin *plus* belladonna alkaloids (as in Donnatal®). Donnagel treats the whole diarrhea

problem. Available on your prescription or recommendation.

For acute, non-specific diarrheas
Donnagel® -PG (Donnagel with paregoric equivalent).
 Donnagel formula plus powdered opium, USP, 24.0 mg. (equivalent to paregoric 6 ml.) (warning: may be habit forming). Alcohol, 5%.

All the antidiarrheal benefits of paregoric without the unpleasant taste. Real banana flavor makes it acceptable, even to children. See product literature before prescribing.
 A. H. Robins Company
 Richmond, Va. 23220

A·H·ROBINS

CLEAR THE TRACT! ROBITUSSIN

THERE'S A FORMULATION FOR EVERY COUGHING NEED

All the Robitussins contain glyceryl guaiacolate, the outstanding expectorant agent that greatly increases the output of lower respiratory tract fluid. Increased RTF volume exerts a demulcent effect on the tracheo-bronchial mucosa, promotes ciliary action, and makes thick, inspissated mucus less viscid and easier to raise.

For coughs of colds and "flu"

ROBITUSSIN®

Each 5 cc. contains:

Glyceryl guaiacolate 100 mg.
Alcohol, 3.5%

For unproductive allergic coughs

ROBITUSSIN® A-C

Each 5 cc. contains:

Glyceryl guaiacolate 100 mg.
Pheniramine maleate 7.5 mg.
Codeine phosphate 10.0 mg.
(warning: may be habit forming)
Alcohol, 3.5%

Non-narcotic for 6-8 hour cough control

ROBITUSSIN®-DM

Each 5 cc. contains:

Glyceryl guaiacolate 100 mg.
Dextromethorphan hydrobromide . . 15.0 mg.
Alcohol, 1.4%

New! Clears sinuses and nasal stuffiness as it relieves cough

ROBITUSSIN®-PE

Each 5 cc. contains:

Glyceryl guaiacolate 100 mg.
Phenylephrine hydrochloride . . . 10.0 mg.
Alcohol, 1.4%

A-H-ROBINS

What's New!

A solid form of Robitussin will be introduced in early October by the A. H. Robins Company. Named "Cough Calmers," the cherry flavored lozenges will be available in units of 18 and each lozenge will contain the equivalent of one-half teaspoonful of Robitussin-DM.

* * * *

The "Doptone" Blood Flow Detector may now have found a new application in the diagnosis of venous problems in the leg. Manufactured and marketed by the Smith Kline Instrument Company of Philadelphia, the Doptone instrument was originally introduced for use in detecting arterial obstruction, but its role in the diagnosis of venous obstruction is also being studied.

* * * *

Alliance Laboratories, Inc., represents an effort on the part of fourteen independent drug wholesalers to manufacture a broad line of quality generic pharmaceuticals.

* * * *

The latest wrinkle in bedside chemical analysis has recently been introduced by the Ames Company. AZOSTIX are clear plastic strips which react with one drop of capillary or venous blood to provide a semiquantitative estimate of blood urea nitrogen.

* * * *

The Ulmer Pharmacal Company, Minneapolis, Minn., introduces ULVICAL Plus, a vitamin/mineral supplement specially formulated for women during pregnancy and lactation.

Phosphorous-free ULVICAL Plus is a high-calcium, vitamin/mineral formula in "one-a-day" tablet form. The vitamins in ULVICAL Plus include 15 I.U. of Vitamin E to protect unsaturated fatty acids from peroxidation during storage of the fatty acids in body cells. A decrease of vitamin E in the blood increases the fragility of red blood cells. The formula includes the necessary, not in excess, vitamins and minerals commonly needed during pregnancy.

Utopia?

Oscar Wilde once said: "A map of the world on which the country of Utopia is not marked deserves no glance, for it leaves out the shores on which mankind will eternally land. And when mankind arrives there, it looks around for a better land and sets sail for it."

The Semisynthetic Penicillins

THE SUBJECT of the semisynthetic penicillins has been reviewed previously.¹⁻⁴ The present report represents an effort to bring this subject up to date. The sharing of 6-amino-penicillanic acid (6-APA) as a nucleus, cross-allergenicity, and a bactericidal effect on susceptible microorganisms characterize the group of antibiotics known as the penicillins. The penicillins appear to act by interfering with the transfer of muramic acid and the subsequent synthesis of mucopeptides that are essential for the formation and integrity of the cell walls of susceptible microorganisms. These drugs apparently act only on growing cells and appear to be inactive against resting microorganisms.⁵

The naturally occurring penicillins are produced by fermentation of several species of molds, including *Penicillium notatum* and notably a strain of *Penicillium chrysogenum*. On identification of the penicillin nucleus, the semisynthesis of the penicillins became possible, and the clinical characteristics of these drugs reflect the chemical addition of various side chains to the 6-APA nucleus.

Of the naturally occurring drugs, penicillin G generally is preferred to penicillin V in more serious infections. With the recognition of cross-allergenicity, penicillin O is no longer commonly used. There are other natural penicillins such as F, K, N, and X, which have no current clinical application. In general, infections previously responding to penicillins G and V continue to respond, except those due to certain staphylococci.^{6,7}

The natural penicillins eluded chemical identification until 1958, when Seehan constructed the penicillin nucleus, 6-APA, a fused beta-lactamthiazolidine ring system that has a carboxyl group at carbon 3 and an amino group at carbon 6. The molds, which produce the natural penicillins, produce the nucleus before attachment of the side chains. Procedures were

developed that inhibited attachment of the side chains, thus stopping production of the molds just after the unattached nucleus had been produced. The fermentation process was scaled up in order to produce 6-APA in large quantities, and organic chemists began adding various side chains. An alternative method for producing 6-APA is employment of amidase (acylase) enzymes to remove the side chain from readily obtainable penicillins. These penicillinamidases or penicillinacylases are of fungal and bacterial origin.⁸

The first commercial example of the semisynthesis of penicillins was phenethicillin, but a more monumental accomplishment was the semisynthesis of the penicillinase-resistant methicillin in 1960 by Doyle. Further search has led to other semisynthetic penicillins, but these drugs appear to be only bellwethers of even newer derivatives that have possible clinical application.

The preparations of the penicillins are available for oral and parenteral administration, but their topical application should be avoided. This is so because indications for their topical use are virtually nonexistent, and consequent hypersensitization to the penicillins, when used in this fashion, is not infrequent. Also, despite considerable speculation, it is not known whether a constant level of these drugs in serum is more or less effective than a varying concentration. As a generalization, the penicillins enter ascitic fluid and cross the placental barrier, but their diffusion into body cavities and fluids is poor unless they are given in large doses or inflammation is present. Compared to methicillin, oxacillin may be characterized by its relative inability to diffuse into some body cavities and fluids.

Phenethicillin (Phenoxyethyl Penicillin)

Phenethicillin (Syncillin, Darcil, Maxipen,

Semopen) is relatively resistant to gastric acid and hence can be given orally. Phenethicillin is a homologue of penicillin V (phenoxymethyl penicillin), from which it differs by the addition of a methyl group in the side chain. However, in contradistinction to potassium penicillin V, the absorption of phenethicillin from the intestinal tract is more likely to be reduced when the drug is taken with food or shortly after food has been consumed. Phenethicillin may produce higher serum levels than penicillin V, but data indicate that there is no difference, weight for weight, in their antibacterial effects on serum bactericidal testing.⁹ Therefore the drugs may be used more or less interchangeably, although phenethicillin, unlike potassium penicillin V, should be administered when the patient's stomach is empty. Peak levels in serum are attained in about one hour and persist for about four hours. Phenethicillin, like penicillin V, is inactivated by penicillinase; binding of the two drugs by serum protein is similar and amounts to 50 to 75%. Phenethicillin, like penicillin V, is used in mild to moderately severe infections and is given in a similar dosage. A dose of 125 mg., or 200,000 units, may be given at four- to eight-hour intervals, but 500 mg. or more has been given even more frequently.

Methicillin

This drug is employable against penicillin G-resistant staphylococci because methicillin (Staphicillin, Dimocillin-RT) is not appreciably inactivated by staphylococcal penicillinase and, consequently, is active against staphylococci which, *in vitro*, require more than 1.0 μ g. of penicillin G for inhibition. However, methicillin is only about a third as effective as penicillin G against susceptible organisms and, like oxacillin, cloxacillin, and nafcillin, is virtually inactive against enterococci. Occasionally, an infection that appeared susceptible on *in-vitro* testing has persisted despite optimal therapy with methicillin; but, to some extent, this has been true of all antimicrobial drugs, including the other available penicillinase-resistant penicillins.

The drug is unsuitable for oral administration and is given intravenously or intramuscularly. Serum levels reach a peak from 30 minutes to one hour after intramuscular adminis-

tration. With single intramuscular doses, serum concentrations tend to decrease rapidly and may decline below the therapeutic range after three to four hours. After intravenous injection, the initial level is higher but declines more rapidly. Nearly half the injected dose is excreted in the urine within the first six hours after administration; like the other available penicillins, methicillin is excreted chiefly via the renal tubules. Methicillin is found in bile and enters other body fluids slowly.

In patients with renal insufficiency, serum levels may persist for 10 hours or longer. In very young infants, apparently because of inadequate renal reserve, the excretion of the penicillins, including methicillin, may be delayed for days, and a correspondingly high and sustained blood concentration may be present. As is true of the other available penicillins, serum levels of methicillin are not appreciably influenced by hemodialysis. Approximately 20% of methicillin is bound to plasma proteins.

The mechanism of penicillinase-resistance of methicillin and allied drugs is not known, but presumably the side chains of these penicillins prevent the splitting of the beta-lactam ring of the 6-APA nucleus. The theory of "steric hindrance" proposes that the two methoxy groups in the side chain of methicillin disallow effective contact of the ring by the enzyme.

Strains of staphylococci isolated from patients in British hospitals have been resistant to methicillin¹⁰ and cross-resistant to some of the kindred drugs, including oxacillin,¹¹ cloxacillin,¹¹ and nafcillin.¹² There is fear that indiscriminate use of these drugs may lead to an increase in such resistant strains in this country. Not only may staphylococci emerge as being resistant to methicillin by a nonpenicillinase mechanism, but methicillin also is a powerful inducer of penicillinase production. Consequently some workers have expressed concern that widespread use of methicillin may result in an increased incidence of high penicillinase-secreting staphylococci that are resistant to all the commercially available penicillins.⁵

Methicillin is given intravenously by intermittent injection in amounts of 1 to 2 Gm. every two to six hours. Methicillin should not

be added to large quantities of infusion fluids, which are often sufficiently acid to cause inactivation over a period of several hours. A dose of 0.5 to 1 Gm. can be given intramuscularly every four to six hours; a dose of 1 Gm. can be injected intramuscularly in 1.5 to 2 ml. of distilled water.

Intrapleural and intra-articular injections of 0.5 to 1 Gm. of methicillin, dissolved in 5 to 10 ml. of sterile normal saline, have been given daily to patients with infections due to susceptible organisms. Methicillin also has been administered as an aerosol to combat selected staphylococcal infections of the lung. A dose of 0.5 Gm. of the drug can be dissolved in about 3 ml. of distilled water and inhaled during a period of about 20 minutes four times daily by use of a pump and nebulizer. Methicillin has also been used in the form of eye drops or eye ointment at a 1% concentration.

Oxacillin

This drug (Prostaphlin, Resistopen) is penicillinase-resistant but is also relatively acid-resistant; hence it can be given orally as well as parenterally. Oxacillin is much more resistant to gastric acid than is penicillin G and only somewhat less resistant than penicillin V. Although oxacillin may be slightly less resistant to penicillinase, its antistaphylococcal effect is significantly greater than that of methicillin.^{13,14} Because of the nature of its side chain, oxacillin is known as an isoxazolyl penicillin.

When oxacillin is given orally in a single dose, peak serum levels occur in different persons after intervals varying from 30 minutes to two hours. Food interferes with the absorption of oxacillin and decreases its serum levels. On oral administration of oxacillin, considerable variation in serum levels and their duration occurs in the same person, as well as among different persons, and occasionally no serum levels are demonstrable. Such erratic serum levels have considerably tempered initial enthusiasm for oral use of the drug. As a generalization, after oral administration, the serum levels of oxacillin persist for about four hours. In contradistinction to methicillin, in patients having renal insufficiency, the persistence of oxacillin in the serum may be only slightly prolonged. With intramuscular ad-

ministration, peak serum levels usually occur in 30 minutes and persist four to six hours; 0.5 Gm. given intramuscularly produces blood levels comparable to those obtained on administration of 1 Gm. by mouth. Significant accumulation of oxacillin in serum does not appear to occur with recommended doses every four hours by either the oral or the parenteral route. After intravenous administration, levels of oxacillin in blood are higher than after intramuscular injection, but decline more rapidly—that is, in less than four hours.

Oxacillin and the allied drug cloxacillin are bound to serum proteins to a greater degree (80% or more) than are other commercially available penicillins.

Oxacillin is five to eight times more effective than methicillin against pneumococci and susceptible streptococci but is not as effective as penicillin G on a milligram-for-milligram basis. Although oxacillin is not the drug of choice for the treatment of infection due to these organisms, when given in doses sufficiently large to inhibit penicillase-producing staphylococci, it may be capable of controlling pneumococcal and most streptococcal infections. Therefore, some workers believe it may be unnecessary to give penicillin G conjointly to control infections which might be due to pneumococci and most streptococci before microbiologic data are reported. However, it is advisable to use penicillin G or V in proved pneumococcal or streptococcal infections. Similar conclusions have been made regarding use of nafcillin and cloxacillin by certain investigators.

Oxacillin does not appear to be excreted well in sweat, may not diffuse readily into certain body cavities, and may not be present in substantial amounts in some body fluids. It does appear in bile, pleural and amniotic fluids, and milk. The extrarenal inactivation of oxacillin seems to be greater than that of methicillin. The higher biliary excretion of oxacillin, compared to methicillin, may account for the somewhat lower urinary recovery of oxacillin. Nafcillin and cloxacillin resemble oxacillin in that they appear in relatively high concentration in the bile.

Oxacillin is given in oral doses of 0.5 to 1 Gm. four to six times daily, preferably when

the patient has an empty stomach. The usual daily intramuscular dose also is 0.5 to 1 Gm. every four to six hours. In severe infections, oxacillin is given intravenously every two to six hours in amounts of 1 to 2 Gm. This amount of the drug can be dissolved in 10 to 20 ml. of 5% dextrose or normal saline solution and injected during a period of several minutes. As an alternative method for intravenous use, the drug can be dissolved in 100 to 200 ml. of an isotonic solution and given during a one- to two-hour period. Oxacillin is more resistant than methicillin to deterioration in solutions prepared for intravenous use.

Nafcillin

In contradistinction to the isoxazolyl penicillins, such as oxacillin, nafcillin (Unipen) has an ethoxynaphthyl side chain. On oral administration, nafcillin produces serum levels that may be somewhat lower than those attained with oxacillin, but nafcillin persists longer in the serum and may provide better penetration of tissue. Like oxacillin and cloxacillin, nafcillin is absorbed poorly from the intestines in some patients, and serum levels are higher when the patient is fasting or has had repeated doses.¹⁵ After oral administration, peak serum levels of nafcillin are attained within one to two hours; after intramuscular injection they are attained in 30 minutes. Serum binding of nafcillin amounts to about 60% and therefore is less than that with oxacillin or cloxacillin but greater than that with methicillin. Only 5 to 10% of an oral dose is excreted in the urine during the first 12 hours, but 30 to 50% of an intramuscular dose is so excreted. The concentration of nafcillin in bile may be several times that in serum. Traces of the drug can be detected in synovial fluid. Its *in-vitro* antibacterial activity exceeds that of methicillin and approximates that of oxacillin.

Despite the availability of similar drugs, continued availability of nafcillin, especially preparations of the drug for parenteral administration, appears desirable because of the concentration and persistence of nafcillin attained in the body tissues.

The oral dose of nafcillin is 0.5 to 1 Gm. every four to six hours when the patient's stomach is empty. When administered intra-

muscularly, 0.5 to 1 Gm. also is given every four to six hours. A dose of 1 to 2 Gm. is given every two to six hours intravenously in the manner previously noted for oxacillin.

Cloxacillin

Like oxacillin, cloxacillin (TegoPen) is an isoxazolyl penicillin and differs chemically from the latter only in that it has a chlorine atom in its structure. Serum levels after oral administration of cloxacillin are at least twice as high as those after oxacillin use;^{16,17} but cloxacillin is more rapidly excreted.

Indications

Unlike methicillin, cloxacillin is less effective against a large inoculum than against a small one, probably because the drug is less resistant to staphylococcal penicillinase than is methicillin. On *in-vitro* testing, cloxacillin is less active than penicillin G, five to ten times more active than methicillin, and about twice as active as oxacillin.

Dosage

After oral administration, peak serum levels of cloxacillin are usually attained in about one hour and persist four to six hours. As aforementioned, in some patients the drug is poorly absorbed from the intestines, or not at all, and serum levels are lower in the nonfasting state. Accumulation of cloxacillin in serum does not appear to occur after multiple doses. Twenty-five to 30% of a given dose is excreted in the urine within six hours, and significant amounts are excreted in the bile.

In the study of Sidell and co-workers¹⁸ on intramuscular administration, cloxacillin, oxacillin, and nafcillin were equally active when absorption, serum antistaphylococcal activity, and serum binding were combined in a single assay method.

A preparation of cloxacillin for parenteral use is not commercially available in the United States. The oral dose of cloxacillin varies from 0.25 to 1 Gm. given every four to six hours when the patient's stomach is empty.

Ampicillin

This drug is orally and parenterally ad-

ministered and has an alpha-aminobenzyl group in place of the benzyl side chain of penicillin G.

Indications

Ampicillin (Polycillin, Omnipen, Penbritin, Principen) is active against more than 80% of strains of *Escherichia coli* and against about 90% of strains of *Proteus mirabilis*; it is likewise effective against certain strains of other gram-negative bacilli such as *Haemophilus influenzae*, *H. parainfluenzae*, *Salmonella*, *Shigella*, *Brucella*, and *Bacteroides*. The drug is also active against *Neisseria*, *Clostridia*, pneumococci, and streptococci. However, it is inactive against penicillin G-resistant staphylococci, as well as against most strains of *Klebsiella-Aerobacter*, indole-producing *Proteus*, and *Pseudomonas* organisms. Ampicillin and phenethicillin are considerably more active than the other available semisynthetic penicillins against enterococci. Also, ampicillin may have an anti-enterococcal effect even greater than that of penicillin G, at least against certain strains of these microorganisms.¹⁹ Ninety per cent or more of strains of enterococci are susceptible *in vitro* to ampicillin; streptomycin or kanamycin may enhance the anti-enterococcal effects of ampicillin.

On oral administration, levels of ampicillin in serum and urine do not appear to be greatly lessened when the drug is taken with food.²⁰ After oral administration, peak levels in serum are reached in about two hours and trace levels are present for at least six hours. When the drug is given intramuscularly, peak levels in serum are achieved in 30 minutes to one hour, and the levels are considerably higher and more prolonged. Intravenous injection of ampicillin produces higher peak levels in the serum and more rapid excretion of the drug than does intramuscular administration.²¹ In patients with renal insufficiency, the duration of serum concentration of ampicillin may be half again as long as that in normal subjects. Susceptible gram-negative bacilli are inhibited by feasible levels of ampicillin in serum—that is 5 μ g. of the drug per milliliter or less. Ampicillin is bound to plasma proteins only to the extent of about 10 to 20%.

The concentration of the drug in the bile

may be 300 times that in the plasma. High concentrations of ampicillin also appear in the urine.

Although good results have been obtained in some patients with systemic infections from *Salmonella*,²¹ ampicillin has not as yet displaced chloramphenicol as the drug of choice in acute typhoid fever; there are some indications, however, that the relapse rate in typhoid fever after use of ampicillin is lower. Contrariwise, ampicillin is much more effective than chloramphenicol in eradicating the typhoid carrier state.²² Fecal or urinary excretors of *Salmonella* organisms are more likely to respond to ampicillin therapy than are biliary excretors; biliary excretors without cholelithiasis respond better than those with stones, but after cholecystectomy at least half will respond.

The drug has been effective in meningeal, respiratory, urinary, and other infections due to susceptible microorganisms. Because ampicillin is active against *H. influenzae*, meningococci, and pneumococci, it is being investigated as a single agent in the initial treatment of patients suspected of having acute bacterial meningitis before the report of definitive microbiologic data, and thus far, results are encouraging.^{23,24} Ampicillin also has been effective in cases of bronchitis and pneumonia due to *H. influenzae*. The drug has eradicated urinary infections and bacteremia due to *E. coli*, *P. mirabilis*, and enterococci. Data indicate that, in enterococcal bacteremia and endocarditis, ampicillin may approach the efficacy of combined streptomycin-penicillin G therapy.¹⁹ As aforementioned, the anti-enterococcal effect of ampicillin may be enhanced by conjoint use of streptomycin or kanamycin. Ampicillin may be preferred to the tetracyclines under certain circumstances, as in pregnant women and infants, in order to avoid tetracycline-induced adverse reactions which are likely to occur in such patients. Ampicillin also has been recommended as an alternative drug to the tetracyclines in the management of intestinal malabsorption²⁵ and in the treatment of pertussis.²⁶

Dosage

A dose of 0.5 to 1 Gm. of ampicillin is given

every four to six hours orally. It has been given parenterally in the same dosage, but higher doses are not uncommon. The stability of sodium ampicillin may decrease markedly with increases in its concentration, and the storage of injection solutions may be hazardous. Five to 25% of the initial potency of the drug may be lost within a few hours, even when solutions are stored at refrigeration temperatures. The presence of dextrose and lactate in solutions of ampicillin may further accelerate loss of the drug's potency.

A dose of 500 mg. of ampicillin dissolved in 5 to 10 ml. of sterile normal saline has been given by intrapleural and intra-articular injection. Ampicillin also has been used in the form of eye drops or eye ointment in a 1% concentration.

There are other semisynthetic penicillins that have reached the stage of preliminary clinical investigation, examples of which are dicloxacillin^{27,28} and hetacillin.²⁹

Dicloxacillin

Like oxacillin and cloxacillin, dicloxacillin is one of the isoxazolyl group of semisynthetic penicillins. Dicloxacillin differs from cloxacillin in having an additional chlorine in the side chain of the phenyl ring. The ability of dicloxacillin to resist gastric acid is similar to that of cloxacillin. There are preliminary indications that methicillin-resistant staphylococci may be inhibited by dicloxacillin; consequently, in infections due to staphylococci which resist the commercially available antistaphylococcal penicillins, dicloxacillin might have special application. On oral and parenteral administration of dicloxacillin, serum levels are twice as high as those after cloxacillin use and four times those after oxacillin use. In the fasting state, oral doses produce serum levels that persist about four hours. Serum levels after intramuscular administration of dicloxacillin may not be much higher and only slightly more prolonged than after oral administration, but are more reliable. Intravenous administration of dicloxacillin produces higher initial levels in serum than follow intramuscular injection, but the drug is eliminated more rapidly.

Preliminary studies in human staphylococcal

infections indicate that dicloxacillin is at least as effective as the commercially available drugs.

The usual oral and intramuscular dose of dicloxacillin is 0.25 to 0.5 Gm. given every four to six hours; 1 Gm. or more has been given every two to four hours intravenously.

Hetacillin

This drug is derived from an acylation condensation procedure in the synthesis of ampicillin. Hetacillin and ampicillin have similar antibacterial spectra and appear to have at least comparable potency; hetacillin is also hydrolyzed by penicillinase. When equal oral doses are given, serum levels on use of hetacillin exceed those of ampicillin after the fourth hour. When given intravenously, hetacillin is said to produce serum concentration considerably higher than that after injection of ampicillin. The renal clearance of hetacillin is similar to that of ampicillin, and the appearance in the urine of a larger proportion of the administered dose of hetacillin has been taken to indicate an even greater resistance to extrarenal destruction than is true for ampicillin. Hetacillin has been effective in bacteremia due to *E. coli*, pneumonia due to *Diplococcus pneumoniae* and *H. influenzae*, urinary infections due to susceptible gram-negative bacilli, shigellosis, and salmonellosis. It has been concluded that 6 Gm. of hetacillin per day should be therapeutically equivalent to 8 Gm. of ampicillin. It is conceivable that in the future hetacillin may be preferred to ampicillin because of the better utilization of hetacillin in human subjects.

Untoward Effects

Allergy is the major untoward effect encountered on use of the penicillins and may be present in 3 to 5% of the general population and in as many as 10% of patients who previously have been treated with the drugs. Cross-allergenicity among the natural penicillins and the semisynthetic penicillins apparently reflects the 6-APA nucleus which they have in common. It is theorized that catabolic products of the penicillins, such as penicilloyl compounds, may unite with body protein and be responsible

for some of these allergic reactions. It is also possible that a macromolecular protein or peptide residue in the penicillins is responsible for some of these reactions. This impurity may result from certain procedures in the manufacture of the drugs and may be removable by dialysis or column fractionation.^{30,31}

Oral administration of a penicillin is least likely to induce allergy, topical application is most likely, and injection is of intermediate capacity in this regard. Methods employed in attempts to identify allergic subjects include skin testing with the drugs as well as with the derivative penicilloyl-polylysine, conjunctival testing, and tests of passive transfer, serum hemagglutination, and indirect basophilic degranulation; none of these, however, is totally reliable. Persons with a history of such conditions as asthma, eczema, or hayfever are more likely to demonstrate hypersensitivity, particularly anaphylaxis, on use of the penicillins. The genesis of penicillin allergy is complicated by sources of inadvertent acceptance of the drugs, such as milk, fowl, and viral vaccines.

Desensitization may aid in avoiding further reactions to the penicillins. Such substances as antihistaminics, epinephrine, penicillinase, and corticosteroids may help in their management. However, penicillinase may also cause allergic reactions, and the enzyme would probably not be helpful in cases wherein a penicillinase-resistant drug is causative. Although corticosteroids are of use in allergic states, the presence of infection sometimes makes it hazardous to use such drugs.

It is common experience that various skin reactions, including contact dermatitis, angio-neurotic edema, glossitis, hairy tongue, stomatitis, thrush, pruritus ani and vulvae, drug fever, eosinophilia, serum sickness, and anaphylaxis, may complicate use of the penicillins. The incidence of fatality in anaphylaxis is estimated to approach 10%. More unusual reactions include purpura, pericarditis, toxic psychoses, hematemesis due to an urticaria-like reaction of the gastric mucosa, and diffuse vasculitis. Gastrointestinal irritation, including diarrhea, may occur after the use of an orally administered penicillin but is seldom severe enough to require discontinuation of therapy. Pain on intramuscular injection of the semi-

synthetic penicillins is more likely on use of ampicillin and nafcillin. Sterile abscesses rarely occur at the site of intramuscular injections of the penicillins. Chemical phlebitis on intravenous administration is most commonly associated with use of nafcillin.

In patients requiring sodium restriction, such as those with heart failure or renal dysfunction, who are receiving one of the semi-synthetic penicillins, the increased intake of sodium should be considered. In such cases, one should recall that each 4 Gm. of methicillin supplies 230 mg. or 10 mEq. of ionic sodium.

Granulopenia and anemia have occurred after administration of methicillin,³² and oxacillin and cloxacillin have caused transient leukopenia.⁵

The penicillins, when given in large amounts, may cause cortical irritation, including convulsions, especially in patients with decreased renal function. Chronic brain damage may result. Since the penicillins, in addition, have precipitated acute psychosis, and since anaphylactic reactions have also resulted in chronic brain damage,³³ perhaps one should be more aware of the potential neurotoxicity of these drugs.

It appears increasingly likely that methicillin has significant nephrotoxicity.³⁴

The significance of increased activity of serum transaminase during therapy with ampicillin, oxacillin, and cloxacillin remains unclear. Oxacillin has been accused of causing hepatic toxicity,³⁵ including cholestatic hepatitis.³⁶

Food interferes with the intestinal absorption of phenethicillin, oxacillin, cloxacillin and nafcillin, and in some cases the decreased serum levels may be therapeutically inadequate.

The penicillins may depress the coccal members of the body flora, thereby encouraging bacteremia, pneumonia, and other infections caused by overgrowth of gram-negative bacilli and *Candida*. Periodic examination of the sputum and stools may reveal changes in the body flora in time to avert clinical superinfection. In series of patients treated with methicillin, as many as a third have experienced superinfection, including fatal bacteremia, due to gram-negative bacilli. Ampicillin-induced superinfections are most frequently due to *Pseu-*

domonas and *Klebsiella-Aerobacter* organisms.

Since strains of coagulase-positive staphylococci, isolated from patients in British hospitals, have been resistant to methicillin and cross-resistant to the commercially available kindred agents, it is feared that when these drugs are used in a given area for a period of time, the incidence of such resistance may increase. This ominous possibility should be sufficient to militate against indiscriminate use of these drugs. Coagulase-negative staphylococci may be even more prone to emerge as being resistant to these drugs.

Although the effect of the penicillins on the fetus is not precisely known, as a generalization, these drugs appear to be nonteratogenic in the human.

The serum levels of all the penicillins, natural and semisynthetic, may be increased on conjoint administration of probenecid; but a number of patients are unable to tolerate this drug because of gastrointestinal irritation.³⁷ Also, side-effects of probenecid may cause confusion with those of the penicillins or with manifestations of the infection being treated. Such side-effects include dermal reactions, anaphylaxis, fever, chills, and anemia. Of course, concomitant administration of probenecid in infections of the urinary tract would not be advisable, since decreased urinary concentration of the antibiotic would be likely.

Present Status

The precise application of the individual semisynthetic penicillins cannot be currently evaluated, and problems of their evaluation undoubtedly will be increased on discovery of still newer derivatives that have possible clinical use. However, of the semisynthetic penicillins which are destroyed by penicillinase, phenethicillin is used more or less interchangeably with penicillin V but, unlike the latter, must be given when the patient's stomach is empty. Ampicillin has proved effective in such infections as influenzal meningitis, bacteremia due to *E. coli*, and systemic salmonellosis and hence has a more assured niche in the current therapeutic armamentarium.

Experiences to date make it clear that methicillin, oxacillin, and nafcillin are efficacious in the parenteral therapy of serious infections caused by penicillin G-resistant staphylococci. Also, oxacillin, cloxacillin, and nafcillin are ef-

fective on oral administration in selected infections due to these organisms. These penicillinase-resistant drugs have given cure rates as high as 70% in some series of staphylococcal bacteremia and have been effective in at least 50% of cases of staphylococcal endocarditis. Many other staphylococcal infections (including pulmonary, skeletal, dermal, and urinary) have been eradicated by these drugs.

Despite their achievements, the overall mortality rate after use of these drugs in patients with severe staphylococcal infections is between 30 and 40%. This rate appears to largely reflect factors in the host responsible for the susceptibility to, as well as the severity of, the infection. In severe staphylococcal infections, such as endocarditis, doses of 8 to 24 Gm./per day or greater are usually necessary for cure; treatment of endocarditis is continued for at least three to four weeks.

The effectiveness of a penicillinase-resistant penicillin depends on at least two properties: (1) its inherent antistaphylococcal potency, and (2) its degree of resistance to penicillinase. The ultimate clinical application of a given drug will be influenced by other factors, including its comparative toxicity on long-term observation.

Of available data on the antistaphylococcal semisynthetic penicillins, the following are noteworthy: They should be used only in selected infections known to be, or highly suspected of being, due to penicillin G-resistant staphylococci; they should not be used in patients allergic to other penicillins; and they should be used cautiously in patients with other allergies, particularly asthma. Higher serum levels of these drugs are required than is necessary with penicillin G, since the agents are less bactericidal than is penicillin G, weight for weight, *in vitro*. However, since the minimal inhibitory concentrations of oxacillin, cloxacillin, and nafcillin³⁸ against pneumococci and streptococci, excepting enterococci, approach those of penicillin G, some workers, at least as an investigational procedure, give one of these drugs as a single agent in infections in which either staphylococci or one of the aforementioned cocci is possibly causative, until microbiologic data are available. In other words, conjoint use of penicillin G or V, theoretically, may be unnecessary under such circumstances;

when the pathogen and its *in-vitro* susceptibilities are known, one switches to a natural penicillin or continues the penicillinase-resistant penicillin, accordingly. This generalization, if supported by further investigation, may be particularly applicable to hospital infections, possibly due to staphylococci.

Discriminate use of the semisynthetic anti-staphylococcal penicillins may help minimize the emergence of resistant bacterial strains and also aid in reducing the problem of allergy to the penicillins.

Because bacterial endocarditis is a potential complication of open-heart surgery, especially when intracardiac prostheses are used, the prophylactic administration of a penicillinase-resistant penicillin to such patients is being investigated. Although delayed infection may sometimes occur from exogenous sources, in most cases it appears to reflect contamination at surgery. Administration of such a drug for 12 to 24 hours before operation and no longer than 72 hours afterward is recommended by some workers in order to avoid undue disturbance of the normal microflora and consequent enhancement of superinfection by resistant organisms on the valve or elsewhere in the body. Conjoint administration of streptomycin is generally not advised, since there is little evidence that an enhanced antibacterial effect is usually achieved thereby, and the likelihood of streptomycin-susceptible gram-negative bacillary infection is remote. Of course, use of a penicillinase-resistant penicillin in this manner will not protect against naturally resistant strains of coagulase-positive staphylococci. Of greater theoretic concern is the finding that coagulase-negative strains appear even more likely to emerge as being resistant to such drugs, and these staphylococci are not an uncommon cause of postcardiotomy endocarditis. It has been theorized that simultaneous use of another antistaphylococcal drug, such as cephalothin, would give broader coverage against resistant staphylococci; but, contrariwise, cephalothin by its conjoint effect on the microflora might further enhance the incidence of postoperative infection due to such organisms as *Candida*. Prophylactic use of a penicillinase-resistant penicillin is also being investigated by some workers in selected neuro-

surgical, orthopedic, and dental procedures.

Oxacillin, cloxacillin, and nafcillin are more active, weight for weight, than methicillin, and consequently the question has been raised whether the continued availability of methicillin is necessary. Also, use of oxacillin may be associated with less likelihood of nephrotoxicity, hematotoxicity, and superinfection than is true with methicillin therapy. However, on comparison with methicillin, oxacillin does not appear to be excreted well in sweat, may not diffuse readily into certain body cavities, and may not be present in substantial amounts in some body fluids; also oxacillin may be hepatotoxic. In this same regard, it is conceivable that oxacillin in turn may be replaceable with cloxacillin because the latter is more active and provides higher and more predictable blood levels. Nafcillin continues to be preferred in certain situations because of its more persistent levels in serum and especially in tissues.

If one supports the concept that the extent of a drug's binding to body protein indicates its ability to inhibit bacterial growth, or the lack of it, one should recall that dicloxacillin, cloxacillin, and oxacillin are highly bound, nafcillin is bound to an intermediate degree, whereas methicillin is least bound. Although some workers have indicated that a drug highly bound to protein may be less available for bacterial inhibition, it is also conceivable that this depot-effect may prolong the drug's antibacterial action.

Summary

Of the commercially available semisynthetic drugs, phenethicillin is used more or less interchangeably with penicillin V. Oxacillin, cloxacillin, and nafcillin are more active weight by weight than methicillin, can be given orally as well as parenterally, and are effective anti-staphylococcal agents. Serum levels of cloxacillin may be twice as high as those of oxacillin. Nafcillin is sometimes preferred because its level persists longer in serum and tissue. Ampicillin has been effective in such gram-negative bacillary infections as influenzal meningitis and bacteremia due to *E. coli*. Long-term evaluation is required to assess the comparative worth of new antibiotics, because

the benefits as well as the untoward effects of a drug may not become known until several years have elapsed after its clinical availability. The increasing number of effective penicillin derivatives and the diversity of their clinical

application, as well as their potential untoward effects, make it incumbent on the practitioner to be familiar with these drugs and to utilize them in a selective manner.

President's Letter

Continued from Page 1777.

I also want to take this opportunity to thank the entire office force of the State Medical Association for their untiring (and many times very tiring) efforts to make our great Organization click. My own personal thanks go especially to Harold Brunn, our outstanding executive secretary, to his girls—Fitz, Marcy, and the rest, as well as to my own chief critic and advisor, Elaine Nye, the Girl Friday to our tremendous Editor-in-Chief, Dr. Carl O. Rice. Few ever get to know of the enormous amount of work which Dr. Rice and his Board of Editors do to make this MINNESOTA MEDICINE of ours one of the outstanding medical journals in the country. I salute all of you!!!

I further wish to extend a world of thanks

and credit to all of our very active Committees. It has been my privilege to attend many Committee meetings; I apologize for not having been able to get to all of them, but time simply would not permit. Our system of checks and balances within the Association will continue to serve us well over a long period of time. No Committee or President can ever get very far out of line!!!

Now, may I wish all of you a Blessed Christmas and a wonderful 1968!!!

C. G. Sheppard, M.D.
President

Abstracts, Briefs and Commentaries

THE MANAGEMENT OF ERYTHROBLASTOSIS FOETALIS MANITOBA—1967

The pathogenesis of erythroblastosis fetalis is reviewed. Of the affected infants approximately 45 to 50% do not require treatment and an additional 25 to 30% should survive and kernicterus be avoided with exchange transfusions. Approximately 20 to 25% of infants will be stillborn or hydropic before term and will require early delivery and, in some cases, intraperitoneal fetal transfusion. Spectrophotometric examination of amniotic fluid has increased the accuracy of ante-natal prediction of severity of fetal affectation from 60 to 95%. In the past five years 749 amniotic fluid studies were performed on 402 sensitized women. Twenty (5%) predictions were inaccurate and only eight (2%) were so inaccurate that the fetus was in jeopardy. Amniocentesis was without significant complications, although a few cases were encountered in which it was suspected that the severity of the fetal disease was increased by the associated passage of fetal erythrocytes into the mother's circulation. In view of the possible risk, amniocentesis is restricted to those patients who have definite risk of fetal death, or about 50% of isoimmunized pregnancies.

In Manitoba 8% of all fetuses with erythroblastosis fetalis would have been stillborn or hydropic before 32 weeks gestation. Intraperitoneal transfusion of the fetus was carried out 128 times in 61 fetuses in the past three years. Twenty-four infants (43%) were salvaged. The salvage rate was 58% if hydropic infants were excluded. In the past 16 months, due to increased experience, these values have increased to 68% and 83%, respectively. The risk of fetal death due to the trauma of the procedure has fallen from 19 to 7%.

The perinatal mortality rate due to erythroblastosis fetalis in the province of Manitoba for the year ending October 31, 1966, was 10.1%; 14 to 138 affected infants died. Four of these deaths were preventable using accepted methods of evaluation and treatment. Five other deaths were probably preventable, as amniotic fluid studies were not obtained or errors were made in management. Four perinatal deaths were not preventable. Optimum management would have resulted in a perinatal mortality rate of 3.6%. This goal is possible only if patients are aware of the need for good prenatal

care and physicians obtain the indicated prenatal antibody tests. Amniotic fluid studies, early delivery and intraperitoneal fetal transfusions may be indicated. The danger of jaundice early in the newborn period must be appreciated. In addition to blood grouping and antibody determinations at the first prenatal visit, the Rh positive woman with no "atypical" antibodies should have blood checked again at 32 to 36 weeks gestation. The unsensitized Rh negative woman should have monthly antibody tests during pregnancy and six weeks post partum. Women with antibodies of any kind should have monthly blood tests until 24 to 26 weeks gestation and then twice monthly and six weeks post partum. Passive administration of Rh immune gamma globulin to Rh negative women without Rh antibodies immediately after delivery of an Rh positive infant shows great promise as a means to prevent Rh isoimmunization. In the near future amniocentesis, early delivery, intraperitoneal fetal transfusion and exchange transfusion may be unnecessary.

IMMEDIATE SURGERY FOR CARDIAC AND GREAT VESSEL WOUNDS

Thirteen patients were treated for wounds of the great vessels or heart. Ten who were treated by surgical exploration and repair survived. Of three treated conservatively (i.e., by pericardiocentesis, tube thoracotomy, etc.), one died. Delay in diagnosis and in definite surgery after diagnosis were two significant errors in management. The simplest, safest, and most effective management of these wounds is immediate thoracotomy and specific therapy. The authors' opinion is contrary to opinions expressed by others who advocate the conservative approach.

A HICCUP REMEDY THAT WORKS

Believe it or not, there's a hiccup remedy that almost always works—but should be used only by physicians.

It involves inserting a flexible tube into a nostril and stimulating nerves in the pharynx, the area at the back of the mouth where nasal passages join the throat.

The process worked in 84 of 85 cases, report three physicians at the University of Chicago School of Medicine and a fourth colleague on the faculty of medicine at Cairo University, United Arab Republic.

Hiccups can be troublesome or even dangerous during surgery. These involuntary contractions of the diaphragm have a variety of causes; and the attempted medical remedies have been almost as numerous as those which come from folklore.

Physicians, too, have tried such remedies as swallowing ice, holding the tongue, frightening with a loud noise, and pressing on the eyeballs. Their results have been about as unpredictable as those of laymen. On a more sophisticated level, they have tried drugs and nerve blockage, often with similar results.

Hiccups seem to occur frequently during light anesthesia. One remedy has been to deepen the anesthesia; however, several times more anesthetic is required to stop hiccups than merely to induce unconsciousness. In some cases, this is undesirable.

Hiccups stopped immediately in 64 anesthetized and 20 conscious persons, the report said, when pharyngeal nerves were stimulated by jerky, back-and-forth movements of the tubing. Patients ranged in age from 18 months to 73 years.

In ten cases, a variety of drugs had failed to stop hiccups, but they ceased almost immediately with the new method, according to the authors. In five cases, the hiccups returned, but stopped during retreatment. Only one anesthetized patient failed to respond to treatment.

A caution should be repeated, however: inserting a tube or other object deeply into nasal passages can be dangerous and should be done only by a physician. Do not attempt this remedy yourself.

The reasons some harmless "home remedies" are sometimes successful—such as swallowing ice or water—may be that they, too, result in stimulation of the pharyngeal nerves, the report points out.

ARTERIAL EMBOLISM—SURGICAL TREATMENT AND RESULTS

Seventy-eight patients underwent surgical treatment for 81 emboli. Myocardial infarction and mitral valve disease with atrial fibrillation was the predominant source. The incidence of excellent results was twice as high if operation were performed before rather than after 12 hours. Conversely, the poor results were almost four times greater if operation was delayed longer than 12 hours. The authors describe their method of localization and removal of the emboli.

PREGNANCY AND HIGH ALTITUDE

Women should stay below the altitude of 10,000 feet in the last three months of pregnancy, advises a Denver physician in the *Journal of the American Medical Association*. The unborn child may be damaged by lack of oxygen if his mother exceeds this altitude in the mountains or in an unpressurized airplane. Skeletal deformities, lack of teeth and hair, brain impairment, and occasionally even death of the fetus have been attributed to lack of oxygen.

"I recommend that women who are pregnant and in the last trimester stay below 10,000 feet in the mountains and that they do not travel in an unpressurized plane while in mountain country. Women in the last three months of pregnancy who are traveling at altitudes over 10,000 feet should breathe supplemental oxygen to protect the fetus if the plane is not pressurized and if travel in an unpressurized plane cannot be avoided," Dr. E. Stewart Taylor wrote.

Most large, commercial planes are pressurized and thus provide the necessary oxygen. A woman in the last three months of pregnancy should consult her physician before flying, however.

AUGMENTATION OF ARTERIAL COLLATERAL BLOOD FLOW

In dog experimentation and computer analysis, the collateral flow into the hind extremities was analyzed with six agents being tested as to their ability to increase the micro-circulatory flow.

Of the agents (heparin and blood volume, plasma, saline, dextran 75 and dextran 40), the best results followed the administration of dextran 40. This seems primarily related to lowering of blood viscosity. The mechanism is still obscure.

A TEN-YEAR EXPERIENCE WITH URETEROILEOSTOMY

One-hundred-ten cases of ureteroileostomy are reviewed with special emphasis on mortality and complications. In sixty-four instances this means of urinary diversion was used to treat a malignant condition; of these, forty-eight patients had carcinoma of the bladder. Ureteroileostomy was employed forty-six times for "benign" conditions, including thirty-three cases of neurogenic bladder dysfunction. Only forty percent of the entire group had an uncomplicated postoperative course. Sixty-four of the procedures done in patients with malignant disease had at least one complication and early postoperative complications were more frequent in this group. There were seven deaths in this group of cases compared to only one death after ureteroileostomy done for a so-called benign condition. Only two ureteroileal leaks occurred in this series and both patients were operated for malignant disease. Eleven of fourteen wound dehiscences occurred in the malignant group and six of eight wound infections. The authors comment particularly on the increased incidence of postoperative complications in those patients who have received preoperative irradiation. It is also of interest that in this series of cases there was only one instance of hyperchloremic acidosis and this was associated with an excessively long ileal loop.

Comment: To those of us who have struggled with these problems, an enlightening and inspiring report.

Book Reviews

Be as careful of the books you read, as of the company you keep; for your habits and character will be as much influenced by the former as by the latter.

SURGERY OF RHEUMATOID ARTHRITIS—Leonard Marmor, M.D., Copyright 1967 by Lea & Febiger, Philadelphia.

During the last few years the orthopedic surgeon has become increasingly involved in the care of the rheumatoid arthritis patient. The old saw of not operating until the disease "burns itself out" is no longer applicable and surgery is now being done in all stages of disease activity. This book represents the personal views of one surgeon who has become especially interested in the rheumatoid patient. Dr. Marmor begins by emphasizing the need of cooperation between the surgeon and internist or rheumatologist, and also the frequent need of other disciplines such as physical therapy, occupational therapy, etc. Much useful information is presented throughout the book, but significant shortcomings exist in the presentation.

The chapter on knee surgery caused the reviewer to raise his eyebrows. It begins with a table listing all of the knee synovectomies the author has done. Of the 34 patients listed only one had any postoperative pain and none had any postoperative swelling of the knee! The longest follow-up is three years, and most of the patients were followed for less than one year. The author's indications for knee surgery are "persistent pain and swelling of the joint or x-ray evidence of joint involvement." This would qualify the vast majority of rheumatoid patients with knee involvement. The author uses a medial and lateral approach for the knee synovectomy, and he states that it is not necessary to remove the synovium from the suprapatellar pouch.

The chapter on hand surgery is well done with respect to technical detail, and the description of soft-tissue (tendon and tendon sheath) involvement is very clear. The author quotes Platt's statement that "the long term results are far too uncertain to justify any pressure being exerted" in urging surgery on one's patient. However, the author speaks quite strongly for the case of surgical intervention. Again Dr. Marmor makes the surprising statement of having had only one recurrence of local disease in 185 operations of synovectomy of fingers. The chapter on hip surgery is largely a discussion of the technique of arthroplasty. The author dismisses the use of femoral head prosthesis as having essentially no place in rheumatoid arthritis of the hip. The chapter on ankle involvement emphasizes tenosynovitis and extra-

articular lesions. The chapter on the foot gives proper emphasis to the Clayton procedure which involves radical resection of the metatarsal-phalangeal joints for forefoot involvement.

All in all the book serves to draw attention to an increasingly important area of surgery. I do not believe the average orthopedic surgeon will want to accept the opinions expressed here as final, but he will use this book as a good starting place to begin his exploration into a growing field of newer help for the rheumatoid arthritic patient.

Minneapolis, Minn.

BIRTH CONTROL AND CONSCIENCE—M. H. Mothersill, M.D.

If conscience is to be effective, it ought to be taught to a child in the early years of life.

To be both wanted and needed ought to be the birthright of every child.

There is too much pity on the part of certain legalistic Christians for the newly fertilized ovum.

Over-population is like a disease; it becomes a vicious cycle. The opponents of birth control are opposed to war but, by their pronatalism, they produce the conditions which make war inevitable.

Twentieth Century Pharisees continue to criticize the use of abortion.

The situation in Japan was such that without abortion the Japanese could not have made the surprising success which they have accomplished.

Many of us would rather be ruined by praise than be saved by criticism.

M. H. Mothersill, M.D.
Indianapolis, Indiana

A TEXTBOOK FOR MEDICAL ASSISTANTS—By Lawton-Foy. 463 pages. Price: \$8.85. Publisher: Mosby, St. Louis, 1967.

For the medical assistant, nurse or secretary who wishes to improve her value to her employer and increase her knowledge, this book is invaluable.

It deals in two parts, first with Business Practices, and second with Clinical Practices, and includes a wide variety of problems that are pertinent in the physician's office.

Carl O. Rice, M.D.
Minneapolis, Minnesota

If it doesn't work in a week, forget it.

Contraindications: Edema; danger of cardiac decompensation; history or symptoms of peptic ulcer; renal, hepatic or cardiac damage; history of drug allergy; history of blood dyscrasia. The drug should not be given when the patient is senile or when other potent drugs are given concurrently. Large doses of Butazolidin alka are contraindicated in glaucoma.

Warning: If coumarin-type anticoagulants are given simultaneously, watch for excessive increase in prothrombin time. Instances of severe bleeding have occurred. Pyrazole compounds may potentiate the pharmacologic action of sulfonylurea, sulfonamide-type agents and insulin. Carefully observe patients receiving such therapy. Use with great caution in the first trimester of pregnancy.

Precautions: Before prescribing, carefully select patients, avoiding those responsive to routine measures as well as contraindicated patients. Obtain a detailed history and a complete physical and laboratory examination, including a blood count. The patient should not exceed recommended dosage, should be closely supervised and should be warned to discontinue the drug and re-

port immediately if fever, sore throat, or mouth lesions (symptoms of blood dyscrasia); sudden weight gain (water retention); skin reactions; black or tarry stools or other evidence of intestinal hemorrhage occur. Make regular blood counts. Discontinue the drug immediately and institute countermeasures if the white count changes significantly, granulocytes decrease, or immature forms appear. Use greater care in the elderly and in hypertensives.

Adverse Reactions: The most common are nausea, edema and drug rash. Swelling of the ankles or face may be minimized by withholding dietary salt, reduction in dosage or use of diuretics. In elderly patients and in those with hypertension the drug should be discontinued with the appearance of edema. The drug has been associated with peptic ulcer and may reactivate a latent peptic ulcer. The patient should be instructed to take doses immediately before or after meals or with milk to minimize gastric upset. Mild drug rashes frequently subside with reduction of dosage. However, rash accompanied by fever or other systemic reactions usually requires withholding medication. Purpuric rash has also been reported. Agranulocytosis, ex-

In rheumatoid arthritis, Butazolidin alka needs only a week's trial. If it doesn't work in a week, forget it.

A short trial period may spare patients weeks of discomfort. That's one reason why Butazolidin alka seems a good choice when aspirin fails.

It's not for every patient. Check carefully the Contraindications, Warning, and Precautions shown below.

And adverse reactions may occur. The most common are nausea, edema and rash. Rarely, agranulocytosis has been reported. All adverse reactions are listed below, too.

You'll know quickly if it works.

And most of the time, it will.

foliative dermatitis, Stevens-Johnson syndrome, or a generalized allergic reaction similar to serum sickness may occur and require permanent withdrawal of medication. Stomatitis, salivary gland enlargement, vomiting, vertigo and languor may occur. Leukemia and leukemoid reactions have been reported. While not definitely attributable to the drug, a causal relationship cannot be excluded. Thrombocytopenic purpura and aplastic anemia may occur. Confusional states, agitation, headache, blurred vision, optic neuritis and transient hearing loss have been reported, as have hyperglycemia, hepatitis, jaundice, and several cases of anuria and hematuria. With long-term use, reversible thyroid hyperplasia may occur infrequently. Moderate lowering of the red cell count due to hemodilution may occur.

Dosage in Rheumatoid Arthritis: Initial: 3 to 6 capsules or tablets daily in 3 or 4 equal doses. Trial period: 1 week. Maintenance dosage should not exceed 4 capsules or tablets daily; response is often achieved with 1 or 2 capsules or tablets daily. 6509-V(B)R2

For complete details, please see full prescribing information.

Butazolidin® alka

Capsules: phenylbutazone, 100 mg.; dried aluminum hydroxide gel, 100 mg.; magnesium trisilicate, 150 mg.; homatropine methylbromide, 1.25 mg.

Also available: Butazolidin®, phenylbutazone: Tablets of 100 mg.

Law and Medicine

Background and Meaning of the McNaghten Case in the Law of Criminal Responsibility

EXONERATION OF CRIMINAL responsibility by reason of insanity is an established social phenomenon taken for granted in Anglo-American law. Debates now rage as to the relative merits of rules which attempt to spell out for judge and jury as precisely as possible when a defendant is to be punished as a criminal and when he is to be held not accountable for proscribed behavior.

There is much opinion as to the scope of testimony of experts such as psychologists and psychiatrists.

It is taken for granted that juries will rely upon the testimony of psychologists and psychiatrists in determining criminal responsibility. This practice and its underlying notions of criminal responsibility have their origin in English common law.

Criminal Responsibility

In general, one was not culpable without the will to commit an offense.¹

In English law² lack of or defective will took four forms.

Subjection to Others

Subjection to the power of others includes the commission of crime prompted by actual force and present fear of death.

Ignorance

Ignorance denotes not ignorance of the law (which one is presumed to know) but only mistake of fact, e.g., intention to kill a thief or housebreaker in one's own home but mistakenly killing a member of one's family.

Infancy

So far as infants were concerned the full age of man or woman by the law of England was 21 years. Under this age a person was termed an infant and exempted from punishment in some cases of misdemeanors and non-capital offenses. Below the age of seven years an infant could not even be punished for a capital offense. Between the ages of seven and 14 years an infant was presumed "to be unacquainted with guilt; yet this presumption will diminish with the advance of the offender's years, and will depend upon the particular facts and circumstances of his case. The evidence of malice, however, which is to supply age, should be strong and clear beyond all doubt and contradiction; but if it appears to the court and jury that the offender . . . could discern between good and evil, he may be convicted and suffer death."² Thus an infant between eight and nine years old was indicted and found guilty of burning two barns and was executed because "it appeared upon examination that he had malice, revenge, craft, and cunning."³

In the case of a nine-year-old who confessed killing a child of the same age it was found that he had hidden the blood and the body. The justices "held that he ought to be hanged; but they respited the execution that he might have a pardon." A child of ten who had killed his companion and hidden himself was actually hanged "upon the ground that it appeared by his hiding that he could discern between good and evil." A girl of 13 was burned for killing her mistress.⁴

Similarly a boy of ten was convicted of murdering a girl about five years of age and

¹Dean's case, 1 Hall 25.³

sentenced to death; although ultimately pardoned, conviction was recommended as a means of deterring other children from like offenses.⁵

Felonies Pardonable for Madness

In 1310 Parliament made felonies pardonable "for madness."⁶ This appears to be the origin of the verdict of *guilty but insane*, a verdict which did not result in acquittal but only granted the right to pardon.

An early pronouncement⁷ of the inclination to set apart a class of defendants not liable to criminal sanction is that of William Lombard of Lincoln's Inn in 1582, which states that criminal responsibility requires a guilty, comprehending mind:

"If a man or a natural fool, or a lunatic in the time of his lunacy, or a child who apparently has no knowledge of good or evil do kill a man, this is no felonious act*** for they cannot be said to have any understanding will."

In *King v. Arnold*⁸ in 1724 the court's charge to the jury was rather stringent:

". . . (N)ot every kind of partial insanity would excuse him, but it must be such a deprivation of reason as made a man no more than a brute or an infant."

In *King v. Lord Ferrers*,⁹ however, the judge charged the jury that it was:

". . . not necessary to have a complete possession of reason but a sufficient degree to comprehend the nature of the action and to discriminate between moral good and evil . . . (and the jury was charged to determine whether defendant was) guilty, judging from his capacity at the moment when he committed the act."

Ferrers plainly repudiated the statement of Coke that "it must be an absolute madness" to excuse treason. On the other hand it accorded with the statement of Hale that the jury was to ". . . judge as in the case of an infant whether there was the power of distinguishing right from wrong."¹⁰

The Lord Ferrers Case

In the case of Lord Ferrers the defendant was found guilty and executed on the ground that the murder was deliberate and that it appeared that when he committed the crime he had sufficient capacity to form a design and know its consequences. The prosecution urged that complete possession of reason was unnecessary to warrant the judgement of the law and that it was sufficient if the party had such

possession of reason as enabled him to comprehend the nature of his actions and discriminate between moral good and evil.¹¹

Lord Ferrers was tried before the House of Lords for the murder of his steward. "It was proved that he was occasionally insane and fancied his steward to be in the interest of certain supposed enemies. The steward being in the parlor with him, he ordered him to go down on his knees, and shot him with a pistol, and then directed his servants to put him to bed. He afterwards sent for a surgeon, but declared he was not sorry, and that it was a premeditated act; and he would have dragged the steward out of bed, had he not confessed himself the villain. Many witnesses stated that they considered him insane, and it appeared that several of his *relations* had been confined as lunatics. It was contended for the prosecution, that the complete possession of reason was not necessary in order to render a man answerable for his act; it was sufficient if he could discriminate between good and evil. The peers unanimously found his lordship guilty."³

Arnold's Case

In Arnold's case the jury found a prisoner guilty of maliciously shooting at Lord Onslow although "it appeared clearly that the prisoner was, to a certain extent, deranged, and that he had greatly misconceived the conduct of Lord Onslow; but it also appeared that he had formed a regular design, and prepared the proper means for carrying it into effect." Here the jury was charged that to exempt a man from punishment it must be shown that he is totally deprived of his understanding and memory and does not know what he is doing any more than an infant, a brute or a wild beast. (At the victim's request, the defendant was reprieved. He was confined to prison until his death 30 years later.)

The Hadfield Case

A brain-damaged war veteran named Hadfield was indicted for treason.¹² He was charged with firing a pistol at George III in Drurylane Theatre on May 15, 1800. On June 18 the defendant brought habeus corpus, averring poverty and requesting assignment

of counsel.* He pleaded not guilty and was remanded** for trial, which commenced on June 26.

In his opening address¹⁰ the Attorney General anticipated the defense of insanity. He stated the law as he knew it:

"If a man be completely deranged, so that he knows not what he does, if he be so lost to all sense that he cannot distinguish good from evil, and cannot judge the consequences of his actions . . . then . . . he cannot be guilty of any crime, because the will which, to a certain extent, is the essence of every crime, is wanting . . ."

The Attorney General cited three exemptions to the foregoing: idiocy, where the defendant cannot discover right from wrong; infancy, where the defendant has not attained the faculty of making such discovery; "temporary frenzy," for example, fever where the defendant cannot comprehend the consequences of his action. He went on to state that the jury was to decide on the state of mind for idiots and children, the latter not to be judged on years alone. The Attorney General also cited Coke, Hale, *King v. Arnold* and *King v. Lord Ferrers*, mentioned above. He admitted that the defendant was "discharged from the military because of mental derangement" but urged that the details of preparation for the commission of the crime showed "thought, design and contrivance in all he did."

Further in support of the last assertion the Crown produced testimony that the defendant had been asked why he made the attempt on the life of the King. The reply was that "he was tired of life and he thought he would certainly be killed if he made an attack on His Majesty's life." It was testified that after the attempt the "defendant seemed perfectly collected." There are repeated references to the defendant's perfect composure and understanding in the testimony of the witnesses for the prosecution.

Medical Testimony on Head Injury

Defense counsel Erskine agreed with the law as stated by the Attorney General but

*One of his assigned counsel, Erskine, already a busy and respected barrister, was later to become one of the most famous trial lawyers in the history of the English bar.

**See Test Your Word Score Page 1823.

stated that in his opinion: "At the moment the fatal catastrophe took place, this unfortunate man did not possess that reason which alone enables a man to distinguish between right and wrong . . ." There was extensive evidence by a surgeon and also by a physician testifying for the defense. To head wounds suffered years previously in battle they attributed recurrent outbursts of the defendant's unreasonable suspicion, gross delusions and uncontrollable violence. A fellow soldier and the defendant's wife both gave evidence of the defendant's grandiose delusions.

The prosecution was surprised by this evidence and agreed readily to the Court's strong suggestion that the defendant be acquitted. The result was essentially a directed verdict for the defendant.

That the prosecution should anticipate the defense of insanity in *Hadfield* is a clear expression of notions of criminal responsibility which are now taken for granted. The second striking feature of this case is the use by the defense of medical experts on the subject of the defendant's sanity.

The Bowler Case

Bowler was tried at the old Bailey in 1812 for shooting at and wounding another. Two weeks earlier he had been found insane by a Commission of Lunacy. There was evidence that following a seizure about one year prior to his trial he had shown "a great alteration in his conduct and demeanor; that he would frequently rise at 9 o'clock in the morning, eat his meat almost raw, and lie on the grass exposed to the rain; and that his spirits were so dejected that it was necessary to watch him, lest he should destroy himself." The jury was charged that it should convict if it found that when he committed the offense he was capable of distinguishing right from wrong and not under the influence of such an illusion as disabled him from discerning that he was doing a wrong act. The jury's verdict was guilty.¹³

The Parker Case—Aiding King's Enemies

Parker's case concerned indictment in 1812 for aiding the king's enemies by entering into the French service in time of war between France and England. The jury convicted after

being urged by the Attorney General that in order to acquit the jury must be satisfied that at the time the crime was committed the prisoner did not really know right from wrong.¹⁴

Bellingham's Case—Gratifying Revenge

In Bellingham's case the jury convicted on the judge's charge that in order to support the defense of insanity it ought to be proved by the most distinct and unquestionable evidence that the prisoner was incapable of judging between right and wrong, that in fact it must be proved beyond all doubt that at the time he committed the act he did not consider that murder was a crime against the laws of God and nature, that there was no other proof of insanity which would excuse murder or any other crime. The trial judge further charged "that in the species of insanity in which the patient fancies the existence of injury and seeks an opportunity of gratifying revenge by some hostile act, if such person be capable in other respects of distinguishing between right and wrong, there would be no excuse for any act of atrocity which he might commit under this description of derangement."¹⁵

"The above direction does not appear to make a sufficient allowance for the incapacity of judging between right and wrong upon the very matter in question, as in all cases of monomania," Roscoe comments on this charge.¹⁵

Monomania

In 1831 Offord was charged with murder by shooting. He had the notion that inhabitants of the town of Hadleigh—especially the deceased—tended to deprive him of his liberty or life by continually issuing warrants against him. Found among his papers was an old summons at the foot of which he had written: "This is the beginning of an attempt against my life." In his pocket he carried a "list of Hadleigh conspirators against my life" with 40 to 50 names thereon, including that of the deceased. Several medical witnesses testified from the evidence they had heard at the trial that the defendant had monomania and that he committed the act while "under the influence of that disorder, and might not be aware that

in firing the gun, his act involved the crime of murder."

The jury was charged that to acquit on grounds of insanity it must find "that he did not know, when he committed the act, what the effect of it, if fatal, would be with reference to the crime of murder. The question was: did he know that he was committing an offense against the laws of God and nature." The jury acquitted him on grounds of insanity.

Non Compos Mentis

In 1840 Oxford was charged with treason. He had discharged a pistol at the carriage containing the Queen and Prince Albert. The carriage passed on, whereupon the defendant discharged another pistol toward it. Both shots missed. Another man was first seized and accused. At this point the defendant said, "It was me, I did it, I surrender myself."

The defendant had imagined himself to be a member of a non-existent, militant secret society and recorded imaginary meetings thereof. Several eminent medical men testified for the defendant, all to the effect that he was of unsound mind.

The jury acquitted him after being charged as follows: "Persons must be taken to be of sound mind until the contrary is shown. But a person may commit a criminal act and not be responsible. If some controlling disease was in truth the acting powers within him, which he could not resist, then he will not be responsible. It is not more important than difficult to lay down the rules. . . . On the part of the defense it is contended that the prisoner was *non compos mentis*, that is (as it has been said) unable to distinguish right from wrong, or, in other words, that from the effect of a diseased mind, he did not know at the time that the act he did was wrong. . . . Something has been said about the power to contract and to make a will. But I think that those things do not supply any test. The question is, whether the prisoner was laboring under that species of insanity which satisfies you that he was quite unaware of the nature, character and consequences of the act he was committing, or in other words, whether he was under the influence of a diseased mind, and was really un-

conscious,* at the time he was committing the act, that it was a crime."¹⁷

The U. S. Law of Criminal Responsibility

The extent to which the foregoing had been incorporated into law in the United States was evident in *U. S. v. Lawrence*. On January 31, 1835, Lawrence fired two percussion pistols at President Jackson.¹⁸ Only the caps of the pistols exploded, evidently owing to the ignorance of the assassin concerning the operation of the weapon.²⁰

A city magistrate made personal inquiry. He found a boarder in the house in which Lawrence roomed who had been convinced for some time that Lawrence was insane. Lawrence had attempted to kill his sister and brother-in-law, and there was evidence of grandiose delusions and paranoid ideation.¹⁹ On February 7, 1835, the marshal of the District of Columbia appointed two physicians to examine the defendant on the question of his sanity. (An editorial comment on the event in the local newspaper presumed Lawrence insane not by reason of the latter's personal history but from the nature of the act alone.²²) Their findings were reported in the local paper.²² However, they made no recommendation as to the defendant's sanity. This was solicited of them by the paper. Their reply cited "... such facts as we suppose would have superseded the necessity of expressing an opinion on the subject of his sanity ... laboring under extensive mental hallucination upon some subjects."

The trial was held on April 11, 1835. Francis Scott Key, prosecuting attorney, cited *Hadfield* and *Arnold* and left little doubt that a verdict of not guilty by reason of insanity would be welcome. The court handed the jury the verdict given in *Hadfield* that the defendant was "... not guilty having been under the influence of insanity at the time he com-

mitted the act." Following his acquittal²³ Lawrence was remanded "to be made as comfortable as possible until further accommodations could be made."

The McNaghten Case

On January 20, 1843, a Scotsman named McNaghten shot Drummond, the private secretary to Prime Minister Peel. Following Drummond's death resulting from the gunshot wound, a preliminary investigation was held on January 30. It appeared that McNaghten was convinced that the Tories were persecuting him; he was certain he had shot Peel.²⁴

At the trial on March 4 before three judges and a jury the Crown presented evidence of deliberate and intentional preparation for the commission of the crime.²⁵

At the conclusion of the Crown's case several physicians testified for the defense.

Dr. Munro testified:

"I do believe that the man was quite deprived of self-control. This deed was the crowning act of the delusion which had haunted him for years. That this may be a partial insanity only, is now clearly established. It may deprive a man of self-control. Monomania is quite distinct from general insanity. Nothing is more common than to find persons of great intelligence on many points quite insane on one point. I heard the evidence yesterday. It does not impair my opinion of his insanity in the least. I have known good arithmeticians among maniacs. I have often found them quite alive to the consequences of their deeds after the committal of them."

"Looking at the whole of this case I consider the prisoner quite capable of judging of the moral impropriety of his act."

Dr. McClure testified:

"My opinion is, that the act committed by him was the consequence of those delusions. From the whole history of the case I consider that his moral liability was destroyed."

Dr. Hutchinson testified:

"I have no doubt that he is laboring under morbid delusions of the mind. I consider that the delusions account for the act he has committed. He was perfectly incapable of exercising control in any matter connected with that delusion, and this act grew immediately out of the delusion."

Dr. Key testified:

"Persons may be laboring under a morbid delusion and yet may be perfectly capable of distinguishing right from wrong, but whatever act the delusion compels him to is quite beyond his moral control."

*Insanity caused by intoxication was not a defense to a criminal charge on the theory that such persons willfully deprive themselves of reason. Roscoe³ gives as an example of the foregoing soldiers "who have been severely wounded in the head who well know that excess makes them mad." "But if, by the long practice of intoxication an habitual or fixed insanity is caused, although this madness was contracted voluntarily, yet the party is in the same situation with regard to crimes, as if it had been contracted involuntary (sic) at first and is not punishable." The author here cites American cases and 1 Hale P.C. 32. Furthermore, although voluntary drunkenness cannot excuse the commission of a crime, where premeditation is at issue, intoxication of the defendant has been held to be a circumstance properly taken into consideration.¹⁸

Mr. Winslow, a surgeon, testified to the same effect.²⁵

Following the medical testimony the chief justice directed a verdict of acquittal.

Contemporary Commentary

Contemporary editorial commentary²⁵ criticized the court's intervention. It argued that in a civil commitment the Court would not prevent the lunacy commission from proceeding to hear further evidence and making its findings of fact. It attacked the physicians for confidently presuming to give an opinion on the state of mind of a person after an event at which they were not present.

Following the acquittal of McNaghten an outraged House of Lords propounded some questions of law to fifteen judges of the criminal courts of England. Their purpose was to clarify the law on criminal responsibility. The judges responded to these questions.²⁶ However, a judge and preeminent 19th century authority on the history of the criminal law of England, Stephen, wrote that the authority of the answers was questionable since it was not a judgment on evidence and the judges were under no obligation to answer the questions.

Partial Delusion

The first question had to do with "partial delusion." For example, a person thinks he is redressing a wrong or producing a public benefit: here the judges stated that he would be guilty "if he was acting contrary to the law of the land."

Question IV also concerned partial delusions. The answer given was that the defendant was to be judged "... as if the (delusion) ... were real." The example given was a person who thinks he is being attacked and defends himself accordingly. This answer assumes the delusion of McNaghten that he was being injured by Peel. Under this rule he would be guilty of first degree murder if he acted upon this delusion. The difficulty, as Stephen aptly points out, is that such delusions rarely stand alone.

Right or Wrong

Questions II and III concerned right or

wrong. Since all are presumed to know the law, this could not encompass solely the law of the land. The answer of the judges was that if the defendant is "... conscious that the act was one which he ought not to do and if that act was at the same time contrary to the law of the land, he is punishable" It would be for the jury to decide "... whether the accused had a sufficient degree of moral consciousness to know he was doing an act that was wrong"

Stephen points out that under this rule Hadfield would have been convicted. He concluded that the effect of delusions goes beyond the rules above promulgated. He notes that the rules are silent on whether the mind might be affected by delusions beyond resulting in mistaken basis for action. He implied that knowledge that an act was wrong might be interpreted in some other sense.²⁷

Stephen opined that madness should attenuate events as fever attenuates murder to manslaughter. He distinguished drunkenness from madness by the fact that drunkenness results from the defendant's own act. It was clear to him that criminal responsibility would not attach to acts occurring in a dream state.²⁸

Mental Disease

Summarizing consideration of criminal responsibility under the McNaghten rules, writing before the turn of the century, Stevens concluded²⁹ that "... the law of England ... is that a man who *by reason of mental disease is prevented from controlling his own conduct* is not responsible for what he does." (Emphasis added.) He concluded that if a narrower view of the rules is taken, madness is just "a possible cause of innocent mistakes."

Irresistible Impulse

Stephen defines self control in terms of the ability to attend distant goals. He also considered the question of irresistible impulse.³⁰ Here he suggested that defendants should be judged to have acted under irresistible impulses by "... whether disease has left them the power of comparing together the different motives by which their conduct may be af-

fects and so making a choice between them.”*

Indefinite Custody

Under the Criminal Lunatics Act of 1800 and the trial of Lunatics Act of 1883 defendants acquitted by reason of insanity in England (“guilty but insane”) were remanded to custody “at his majesty’s pleasure,” i.e., for an indefinitely long period with no right to release.³⁴ In 1964 this was amended to provide commitment as for the mentally ill in civil cases.³⁵

Summary

Prior to 1831 the reported cases on criminal responsibility in England appear to demonstrate that a jury would uniformly convict unless a verdict of acquittal was directed by the Court, as occurred in *Hadfield*.

Beginning with *Offord* and *Oxford*, juries seemed to accept the defense of insanity as more liberally defined by the Court.

*Stephen suggested³² that juries should have a choice of three verdicts in criminal cases: guilty, not guilty and “guilty, but his power of self control was diminished by insanity.”

In Scotland it has long been (and still remains) the law that juries may bring in verdicts of partial responsibility. The court thereupon sentences accordingly.³²

Not until 1957 did the criminal law of England undergo any such modification. In that year Parliament provided³³ for a third alternative verdict in homicide cases only. There the jury could find the defendant not guilty of murder but guilty of manslaughter instead “. . . if he was suffering from such abnormality of mind . . . as substantially impaired his mental responsibility for his acts . . .”

**New York Bar, the District of Columbia Bar and the Minnesota Bar.

Neither *Hadfield* nor *McNaghten* can be said to reflect popular sentiment, however, as both were directed verdicts. Indeed, the reaction of Parliament to the acquittal of *McNaghten* is a truer expression of the popular sentiment. Under the bidding of Parliament, rules were formulated which purported to restore the law of criminal responsibility to its former rigidity as surely as if the rules had been case law instead of extrajudicial pronouncements.

McNaghten brought to full flower the use of medical testimony as to a defendant’s sanity. *Laurence* in the United States reflected the same practice and provoked the same contemporary editorial condemnation. The *McNaghten* rules tend to restrict the scope of such inquiry into a defendant’s state of mind. Yet a foremost 19th century jurist, Stephen, while demonstrating the narrowness of the promulgated rules, unequivocally restated the ruling law of England in terms remarkably modern: one who by mental disease is prevented from controlling his own conduct is not responsible for what he does.

There is merit, therefore, in distinguishing between *McNaghten*, a case culminating in an early liberalizing trend in the law of criminal responsibility, and the *McNaghten* rules, a stultifying influence which persists.

Money will buy a pretty good dog, but it won't buy the wag of his tail.

—Josh Billings

Business is business.

Says who? Says too many people.

You've probably heard it yourself many times.
It's used to justify almost *anything*.

But how many times have you ever questioned this attitude or raised your voice in protest? An idea like this takes root just because not enough people do anything to stop it.

If you have ever asked yourself "Why doesn't someone do something about it?" you're talking to the right person. You.

It won't be easy. Sometimes you'll need encouragement. The kind you'll find in your place of worship.

Here you'll discover you're not alone. That, in itself, can give you the strength to say "Says who?" once in a while when it needs to be said.

Cardiac Resuscitation in a Community Hospital

SHU KANG HO, M.D.*

FRANK QUATTLEBAUM, M.D.**

St. Paul, Minnesota

A CARDIAC RESUSCITATION team can produce rewarding results in the community hospital. Cardiac arrest occurs in all areas of the hospital as well as in removed areas. Often attempts to restore a heart to normal function in the latter situation are futile because of lack of a well organized cardiac resuscitation team.

External cardiac massage was introduced by Jude, Kowenhoven and Knickerbocker in 1960.^{1,2} Prior to this time, cardiac asystole and ventricular fibrillation could occasionally be successfully treated by internal cardiac massage. This technique necessitated a thoracotomy. Applied in the operating room or postanesthesia room, open-heart massage could be rewarding; but if this emergency treatment was applied in an area other than the operating area, the results were rarely successful.

Since the introduction of external cardiac massage, the prognosis in cardiac arrest has been vastly improved.³ The present report is from a community hospital. The authors describe the cardiac resuscitation team organization, its plan of action and the results of the team effort. Bethesda Lutheran Hospital has 300 beds, an active intern program, but no residency program. In 1966 there were 12,000 admissions and 19,600 outpatients. The first patient to receive the benefits of this team effort had a cardiac arrest on April 18, 1964. This study begins on that date and extends through December 31, 1966, a period of 32 months.

Organization

Since the beginning of this effort, one of us (S.K.H.) has participated in many of the resuscitative attempts. In a typical community hospital, the staff members may not be immediately available during certain hours of the day. It has been necessary, therefore, to build the first line of defense around the nurse and

*Anesthesiologist, Bethesda Lutheran Hospital, St. Paul, Minnesota.

**Cardiovascular Surgeon, Bethesda Lutheran Hospital, St. Paul, Minnesota.

the intern. At regular intervals during the year, lectures and demonstrations are given to the nursing and paramedical personnel, and each year the incoming interns are made familiar with the routine. It has been our experience that often the nurse and/or intern recognizes the emergency, sounds the alarm and starts external cardiac massage and oxygenation in less than a minute.

Procedure

As soon as a nurse discovers that a patient has suffered a cardiac arrest, she alerts the hospital switchboard operator to announce the key-call of "Code 99" over the public address system. At the same time, the personnel in attendance place a large chest board beneath the patient and initiate external cardiac massage and artificial respiration.

All members of the resuscitation team respond to the emergency call and often reach the patient in a maximum time of three minutes. Those persons responding to the call include all interns in the hospital at the time (a minimum of two), an anesthesiologist and/or nurse anesthetist, the electrocardiographic technician, the nursing supervisor, and the

head nurse of the nursing station involved. If there are any staff physicians in the hospital at the time, they also respond. Usually the first physician to arrive is an intern who takes command, continues the treatment started by the nurse, and delegates duties to incoming personnel.

Equipment

Chest Board and Ambu Resuscitator

Each of the nursing stations throughout the hospital is equipped with a chest board of 36" by 36" dimension, a tray containing oral airways and an Ambu resuscitator. This equipment is immediately available.

Anesthesia Machine

A portable, easily-moved Ohio-Heidbrink anesthesia machine and a resuscitation cart are kept in the intensive care unit and in the outpatient-emergency section. In response to the emergency call, the nursing personnel in the intensive care unit immediately transport these two items to the scene of emergency.

Resuscitation Cart

The resuscitation cart is equipped with the

TABLE I
Successfully Resuscitated, Discharged From Hospital

Case No.	Age	Sex	Diagnosis
1	68	F	Cerebral arteriosclerotic disease with convulsions
2	65	M	Coronary insufficiency
3	66	M	Postoperative nephrectomy (24 hours postoperatively)
4	70	F	Atrial fibrillation, cardiac decompensation
5	62	M	Carcinoma of the colon
6	60	F	Gastrointestinal bleeding, diabetes mellitus
7	60	M	Allergic reaction to dye for IVP
8	61	M	Asthma, respiratory failure
9	59	F	Congestive cardiac failure
10	59	F	Congestive cardiac failure
11	25	F	Barbiturate overdosage/suicide attempt

17	73	F	Gastrointestinal bleeding
18	72	F	Cerebral thrombosis
19	59	M	Myocardial infarction
20	80	F	Myocardial infarction, cardiac decompensation

Advanced ages and severity of diagnosis of those patients who were successfully resuscitated and discharged from the hospital.

following items: a Morris defibrillator, a small Gomco suction machine, a laryngoscope with a full set of laryngoscopic blades, endotracheal tubes and airways, a sterile tray for doing a venous cut-down, intravenous Ringers lactate solutions, THAM, low molecular weight Dextran and 5 per cent dextrose/distilled water, the necessary syringes, needles and emergency cardiac drugs.

Results

Initial Response

During this study, there have been 119 resuscitation attempts. A total of 48 (40 per cent) cases responded initially to resuscitation. Twenty-eight patients expired during the following days as a result of their condition on admission.

Twenty patients completely recovered and were discharged (Table 1). None of these 20 showed any adverse effects from the arrest or from the resuscitation maneuvers. There was no nervous system impairment. Table 2 summarizes the results of this study, which are comparable to those of Lillehei and associates.³ Forty-five per cent of the patients who eventually left the hospital had originally been admitted with a diagnosis of cardiac disease.

Myocardial infarction was the cause of cardiac arrest in 20 per cent of the successful resuscitations.

Factor of Age

Review of the study reveals that age is no barrier to survival. The average age of the patients on whom resuscitation attempts were made was 61 years. The average age of the patients who were discharged was 66 years. All of the emergencies occurred on the various nursing stations in private and semi-private rooms. None of the reported cardiac arrests occurred in the operating room or recovery room.

The most dramatic result is that of Case 16. This 67-year-old woman was admitted to the hospital with a diagnosis of congestive cardiac failure. A total of 29 episodes of ventricular fibrillation were encountered in a 12-hour period, for which she received 43 defibrillation shocks. She was discharged from the hospital a month later, with no residual effects. The figure depicts an episode of cardiac arrhythmia in this patient that rapidly changed to ventricular fibrillation. Her heart was promptly defibrillated.

Figure—Case 16. Clinical electrocardiographic strip showing in *a*, pacemaker shift to the A-V node with coupled ventricular premature contractions, changing rapidly in *b* to ventricular tachycardia, and in *c*, to ventricular fibrillation.

TABLE 2
Summary of Results 1964-1966

Year	Total Number of Cases	Immediate Death		Response		Discharged	
		Number of Cases	Per Cent of Total	Number of Cases	Per Cent of Total	Number of Cases	Per Cent of Total
1964	35	18	51	17	49	8	23
1965	42	30	71	12	29	5	12
1966	42	23	54	19	46	7	17
Total	119	71	60	48	40	20	17

Results in first 32 months of cardiac resuscitation program. Twenty of the original 119 patients who arrested were discharged from the hospital with no residual effects.

Summary

Rewarding results in cardiac resuscitation can be accomplished through a well organized cardiac resuscitation team in a medium-sized community hospital.

Cardiac resuscitation was achieved in 40 per cent of 119 patients in a 32-month period. Of the 48 patients resuscitated, 20 (17 per cent) were discharged from the hospital. No pa-

tient who ultimately survived exhibited any significant nervous system impairment.

Thus in a 32-month period in this medium-sized community hospital, 20 patients with cardiac arrest were revived and left the hospital in good condition. It is likely that none or very few of these 20 patients would have survived without an organized cardiac resuscitation team.

Errata

Porphyria, Strange and Baffling Ailment, by Drs. Shuman and Snively, concerning laboratory data, 50:10:1467, October, 1967.

The following corrections should be made. Porphobilinogen should be 3.2 mg./100 cc. and would be in the neighborhood of 50 mg. per day, assuming a 1500 cc. output. Delta aminolevulinic acid was 2.6 mg./100 cc., not per cc. On April 2nd, 1963, quantitative coproporphyrin was 3,311 mcg. per 24 hours. On June 14, 1963, porphobilinogen was negative to Watson Schwartz test.

Minnesota State Board of Medical Examiners

Resolutions Adopted by Minnesota State Board of Medical Examiners on August 19, 1967

BE IT RESOLVED, that Minnesota State Board of Medical Examiners proposes that the Rules and Regulations of Minnesota State Board of Medical Examiners be amended in the following particulars:

1. ME 1 (f), by renumbering the same ME 1 (i).

2. ME 1 (g), by renumbering the same ME 1 (j).

3. ME 1, by adding thereto a new paragraph ME 1 (f), reading as follows:

“(f) ‘Medicine’ as used in MSA, § 147.10, shall mean and include any substance or agent which is:

- (1) intended for use or used in the diagnosis, treatment, prevention, mitigation or cure of any disease, bodily injury or infirmity; or
- (2) intended to affect or does affect the structure or function of any bodily organ or system,

whether the intended or actual effect of such substance or agent is at or remote from the site of administration. Except as otherwise expressly authorized by law, any person who for a fee prescribes, directs, or recommends for the use of any person any medicine, as herein defined, shall be deemed to be practicing medicine within the meaning of MSA, § 147.10.”

4. ME 1, by adding thereto a new paragraph ME 1 (g), reading as follows:

“(g) ‘Disease’ as used in MSA, § 147.10, shall mean and include any disorder, impairment, or infirmity in mental or physical ca-

capacity or in the physical, structural, or functional organization or character of any bodily organ or system.”

5. ME 1, by adding thereto a new paragraph ME 1 (h), reading as follows:

“(h) ‘Depressants’ and ‘Stimulants’ as used in MSA, § 147.02, subd. 3, shall include, but not be limited to, those drugs listed and described in MSA, § 152.01, subd. 5.”

6. ME 2, by striking and deleting the whole thereof and substituting the following in lieu and in place thereof:

“ME 2 *Application for Licensure for Medicine and Surgery*

(a) An application for admission to a licensing examination as provided in MSA, § 147.02 (which shall consist of both a written and oral examination, as provided in ME 3), shall be filed with the Board as hereinafter prescribed. If the Board finds that the application is complete and that all of the requirements of MSA, § 147.02, and of these regulations have been met, it shall advise the applicant of the date and place of the examination.

(b) Such application shall be submitted or forms prepared by the Board and shall include the following information:

- (1) If the applicant is a graduate of a medical or osteopathic college duly accredited by the Board, original or certified copy of diploma from such medical or osteopathic college, as the case may be, indicating that the applicant has satisfactorily completed a

- course of study acceptable to the Board and that he has received from such college the degree of Doctor of Medicine, Bachelor of Medicine, Bachelor of Medicine and Surgery or Doctor of Osteopathy.
- (2) If the applicant is currently enrolled in the fourth thirty-six (36) week session at a duly accredited medical or osteopathic college, a transcript of his credits, together with evidence, satisfactory to the Board, that the applicant has satisfactorily completed three entire sessions of a course of study acceptable to the Board of not less than thirty-six (36) weeks each at a duly accredited medical or osteopathic college. Prior to admission to the oral examination, the applicant shall file with the Board the original or a certified copy of diploma from a medical or osteopathic college duly accredited by the Board indicating that the applicant has satisfactorily completed a course of study acceptable to the Board and that he has received from such college the degree of Doctor of Medicine, Bachelor of Medicine, Bachelor of Medicine and Surgery or Doctor of Osteopathy.
 - (3) Original or certified copy of certificate of registration in the basic sciences issued by the Minnesota State Board of Examiners in the Basic Sciences.
 - (4) Evidence satisfactory to the Board of applicant's United States citizenship. In the event applicant is not a citizen, he shall submit, with his application, evidence that he has made a declaration of intent to become a citizen of the United States.
 - (5) A certificate of good moral character signed by two persons licensed to practice medicine and surgery by any recognized and accredited licensing authority within the United States or Canada.
 - (6) An unmounted recent photograph of the applicant with an affidavit on the reverse side thereof made by the applicant that the photograph is that of the applicant.
 - (7) Such other information as the Board shall, from time to time, deem necessary in order to evaluate the qualifications of the applicant.
- (c) An applicant who has passed the written examination in the clinical sciences of the National Board of Medical Examiners and who desires to take the oral examination, shall include in his application, in addition to the information required under ME 2 (b), evidence satisfactory to the Board that within one year before or five years after being granted the degree of Doctor of Medicine, Bachelor of Medicine, Bachelor of Medicine and Surgery or Doctor of Osteopathy, the applicant has satisfactorily passed the examination in the clinical sciences which is prepared, administered and graded in accordance with the provisions of MSA, § 147.02. The Board may, but shall not be required to, recognize and approve the results of such examination in the clinical sciences.
 - (d) An applicant whose credentials are determined by the Board to indicate ineligibility for examination shall be notified of such determination and the grounds therefor and may be granted a hearing thereon in accordance with the provisions of ME 63, by filing a statement of issues with the Board within twenty (20) days after receipt of such notice from the Board. After such hearing the Board shall notify the applicant in writing of its decision thereon.
 - (e) An applicant who has satisfactorily completed both the written and oral examinations, and who has fulfilled all the requirements of MSA, Chapter 147, and of these Rules and Regulations, shall be considered by the Board for licensure to practice medicine and surgery upon submitting to the Board evidence satisfactory to the Board that the applicant has satisfactorily completed either one year of graduate training in an institution in the United States or Canada approved for internship or graduate training by the Board or other graduate training approved by the Board.
 - (f) All applications for examination must be fully completed and forwarded to the Secretary of the Board postmarked not later than thirty (30) days before the date of the examination."

7. ME 3, by striking and deleting the whole thereof and substituting the following in lieu and in place thereof:

"ME 3 Conduct of Examinations Administered by the Board"

(a) Examinations administered by the Board shall be both written and oral. A written examination shall be given in surgery, medicine, obstetrics, gynecology, and such other branches as the Board may from time to time determine. Such written examination in the clinical sciences may be prepared, administered and graded by the Board or prepared and graded by the National Board of Medical Examiners and administered by the Board.

(b) Licensing examinations administered by the Board shall be conducted in accordance with the following rules, and any candidate violating such rules may be dismissed and barred from taking the examination, or may be otherwise disciplined.

(1) During the written examination no applicant shall communicate with any other person in any way except with the express permission of the person or persons conducting the examination.

(2) An applicant shall not bring books or help of any kind into the examination room.

(c) A grade of 75 shall be the passing grade on all examinations graded by the Board. A minimum general average of 75 in all subjects shall constitute a grade satisfactory for licensure. An applicant may fall below 75 in one subject and still be licensed by the Board. If an applicant falls below 75 in more than two subjects, it shall constitute a failure and require that the applicant retake the entire examination with passing grades in order to be eligible for licensure. An applicant failing two subjects may retake the two subjects at the next examination and upon receiving a minimum grade of 75 in each may be eligible for licensure.

(d) Upon the conclusion and grading of the examination, the Board shall prepare a report of the examination results and shall act on the report at its next meeting. The Secretary of the Board shall notify the ap-

plicant of the action of the Board on his application and examination."

8. ME 4 (b) (1), by adding thereto the following sentence:

"If the applicant is a graduate of a foreign medical school, the information required by ME 7 (a) (4) and ME 7 (a) (5)."

9. ME 4 (b) (2), by adding thereto the following sentence:

"If the applicant is a graduate of a foreign medical school, the information required by ME 7 (a) (2)."

10. ME 4 (b) (3), by striking and deleting the whole thereof and substituting the following in lieu and in place thereof:

"(3) Evidence satisfactory to the Board that the applicant has satisfactorily completed either one year of graduate training in an institution in the United States or Canada approved for internship or graduate training by the Board, or other graduate training approved by the Board."

11. ME 4, by adding thereto a new ME 4

(b) (4) reading as follows:

"(4) If the applicant is a graduate of a foreign medical school, evidence satisfactory to the Board that the applicant has been awarded a Certificate by The Educational Council for Foreign Medical Graduates, certifying to the applicant's formal education, his having passed the ECFMG English test and his having passed the ECFMG examination."

12. ME 4, by adding thereto a new ME 4

(b) (5) reading as follows:

"(5) The information required by ME 2 (e); ME 2 (b) (3); ME 2 (b) (4); ME 2 (b) (5); ME 2 (b) (6) and ME 2 (b) (7)."

13. ME 4 (c), by striking and deleting the whole thereof and substituting the following in lieu and in place thereof:

"(c) All applicants for licensure by reciprocity shall be required to pass an oral examination administered by the Board."

14. ME 4, by adding thereto a new ME 4

(d) reading as follows:

"(d) An applicant whose credentials are determined by the Board to indicate ineligibility for licensure shall be notified of such determination and the grounds therefor and may be granted a hearing thereon in accordance with the provisions of ME 63, by

filing a statement of issues with the Board within twenty (20) days after receipt of such notice from the Board. After such hearing the Board shall notify the applicant, in writing, of its decision thereon."

15. ME 5 (a), by striking and deleting the whole thereof and by substituting the following in lieu and in place thereof:

"(a) An application for a license to practice medicine and surgery by endorsement, without written examination, may be made by any applicant who is a diplomate of the National Board of Medical Examiners or of the National Board of Examiners for Osteopathic Physicians and Surgeons, or who has passed a licensing examination given by the appropriate board or agency of any state or country which the Board may from time to time determine to be acceptable, as provided in MSA §147.03; provided, however, that the Board may require the applicant to be examined in such subjects which, in the opinion of the Board, have not been satisfactorily covered."

16. ME 5 (b) (1), by striking and deleting the whole thereof and by substituting the following in lieu and in place thereof:

"(1) The information required by ME 2 (e); ME 2 (b) (3); ME 2 (b) (4); ME 2 (b) (5); ME 2 (b) (6) and ME 2 (b) (7)."

17. ME 5 (b), by adding thereto a new ME 5 (b) (3) reading as follows:

"(3) If the applicant is a graduate of a foreign medical school, evidence satisfactory to the Board that the applicant has been awarded a Certificate by The Educational Council for Foreign Medical Graduates, certifying to the applicant's formal education, his having passed the ECFMG English test and his having passed the ECFMG examination."

18. ME 5 (b), by adding thereto a new ME 5 (b) (4) reading as follows:

"(4) Evidence satisfactory to the Board that the applicant has satisfactorily completed either one year of graduate training in an institution in the United States or Canada approved for internship or graduate training by the Board, or other graduate training approved by the Board."

19. ME 5 (c), by striking and deleting the

whole thereof and by substituting the following in lieu and in place thereof:

"(c) All applicants for licensure by endorsement, except those who are diplomates of the National Board of Medical Examiners or of the National Board of Examiners for Osteopathic Physicians and Surgeons, shall be required to pass an oral examination administered by the Board."

20. ME 5, by adding thereto a new ME 5 (d) reading as follows:

"(d) An applicant whose credentials are determined by the Board to indicate ineligibility for licensure shall be notified of such determination and the grounds therefor and may be granted a hearing thereon in accordance with the provisions of ME 63, by filing a statement of issues with the Board within twenty (20) days after receipt of such notice from the Board. After such hearing the Board shall notify the applicant, in writing, of its decision thereon."

21. ME 6 (b) (6), by striking and deleting the whole thereof and by substituting the following in lieu and in place thereof:

"(6) If the applicant is a graduate of a foreign medical school, evidence satisfactory to the Board that the applicant has been awarded a Certificate by The Educational Council for Foreign Medical Graduates, certifying to the applicant's formal education, his having passed the ECFMG English test and his having passed the ECFMG examination."

22. ME 6 (e), by striking and deleting the whole thereof and by substituting the following in lieu and in place thereof:

"(e) An applicant whose credentials are determined by the Board to indicate ineligibility for such temporary permit or certificate shall be notified of such determination and the grounds therefor and may be granted a hearing thereon in accordance with the provisions of ME 63, by filing a statement of issues with the Board within twenty (20) days after receipt of such notice from the Board. After such hearing, the Board shall notify the applicant, in writing, of its decision thereon."

23. ME 7 (a) (1), by striking and deleting the whole thereof and by substituting the following in lieu and in place thereof:

"(1) The information required by ME 2 (b) (3); ME 2 (b) (6) and ME 2 (b) (7)."

24. ME 7 (a) (3), by striking and deleting the whole thereof and by substituting the following in lieu and in place thereof:

"(3) Evidence satisfactory to the Board of applicant's United States citizenship. In the event the applicant is not a citizen, he shall submit, with his application, evidence that he has made a declaration of intent to become a citizen of the United States."

25. ME 7 (a) (7), by striking and deleting the whole thereof and by substituting the following in lieu and in place thereof:

"(7) If the applicant submits to the Board evidence satisfactory to the Board that he has been awarded a Certificate by The Educational Council for Foreign Medical Graduates, certifying to the applicant's formal education, his having passed the ECFMG English test and his having passed the ECFMG examination, then applicant shall submit evidence satisfactory to the Board that the applicant has satisfactorily completed either one year of graduate training in an institution in the United States or Canada approved for internship or graduate training by the Board, or other graduate training approved by the Board. If the applicant has not been awarded such Certificate by The Educational Council for Foreign Medical Graduates, then applicant shall submit evidence satisfactory to the Board that the applicant has satisfactorily completed either two years of graduate training in an institution in the United States or Canada approved for internship or graduate training by the Board, or other graduate training approved by the Board."

26. ME 7 (b), by striking and deleting the whole thereof and by substituting the following in lieu and in place thereof:

"(b) As used herein, the term 'foreign medical school' shall mean a medical school located outside of the United States and Canada."

27. ME 7 (c), by striking and deleting the whole thereof and by substituting the following in lieu and in place thereof:

"(c) An applicant whose credentials are determined by the Board to indicate ineligibility

for examination shall be notified of such determination and the grounds therefor and may be granted a hearing thereon in accordance with the provisions of ME 63, by filing a statement of issues with the Board within twenty (20) days after receipt of such notice from the Board. After such hearing the Board shall notify the applicant, in writing, of its decision thereon."

28. ME 8 (b) (3), by striking and deleting the whole thereof and by substituting the following in lieu and in place thereof:

"(3) The information required by ME 2 (b) (3); ME 2 (b) (5); ME 2 (b) (6) and ME 2 (b) (7)."

29. ME 8 (c), by adding thereto the following sentence:

"The Board may, but shall not be required to, recognize and approve the results of an examination in the clinical sciences which is prepared, administered and graded by the National Board of Medical Examiners or may administer a recognized and approved examination prepared and graded by the National Board of Medical Examiners, in lieu of preparing, administering and grading the examination itself."

30. ME 8 (d), by striking and deleting the whole thereof and by substituting the following in lieu and in place thereof:

"(d) An applicant whose credentials are determined by the Board to indicate ineligibility for examination shall be notified of such determination and the grounds therefor and may be granted a hearing thereon in accordance with the provisions of ME 63, by filing a statement of issues with the Board within twenty (20) days after receipt of such notice from the Board. After such hearing the Board shall notify the applicant, in writing, of its decision thereon."

31. ME 9 (d), by striking and deleting the whole thereof and by substituting the following in lieu and in place thereof:

"(d) An applicant whose credentials are determined by the Board to indicate ineligibility for examination shall be notified of such determination and the grounds therefor and may be granted a hearing thereon in accordance with the provisions of ME 63, by filing a statement of issues with the Board within twenty (20) days after receipt of

such notice from the Board. After such hearing the Board shall notify the applicant, in writing, of its decision thereon."

32. ME 9 (g), by striking and deleting the whole thereof and by substituting the following in lieu and in place thereof:

"(g) An applicant whose credentials are determined by the Board to indicate ineligibility for registration shall be notified of such determination and the grounds therefor and may be granted a hearing thereon in accordance with the provisions of ME 63, by filing a statement of issues with the Board within twenty (20) days after receipt of such notice from the Board. After such hearing the Board shall notify the applicant, in writing, of its decision thereon."

33. ME 10, by striking and deleting the whole thereof and by substituting the following in lieu and in place thereof:

"ME 10 *Masseurs and Masseuses*

(a) An application for registration to practice massage as provided by MSA, § 148.36 shall be filed with the Board as hereinafter prescribed. If the Board finds that the application is complete and that all of the requirements of the statute and of these regulations have been met, it shall advise the applicant of the time, date and place of the interview.

(b) The application shall be made on forms provided by the Board and shall require the applicant to submit the following information:

- (1) Original or certified copy of birth certificate.
- (2) Evidence satisfactory to the Board of educational qualifications, including original or certified copies of degrees, diplomas or certificates, if any.
- (3) Evidence satisfactory to the Board of practical qualifications to practice massage.
- (4) Evidence satisfactory to the Board that the applicant is of good moral character.
- (5) An unmounted recent photograph with the affidavit of the applicant on the reverse side thereof that the photograph is that of the applicant.

(c) An applicant, prior to registration, shall

be interviewed by the Board in order to determine his eligibility for registration.

(d) An applicant whose credentials are determined by the Board to indicate ineligibility for registration shall be notified of such determination and the grounds therefor and may be granted a hearing thereon in accordance with the provisions of ME 63, by filing a statement of issues with the Board within twenty (20) days after receipt of such notice from the Board. After such hearing the Board shall notify the applicant, in writing, of its decision thereon.

(e) The Board, in its discretion, may register a person to practice massage in this state who holds a license from any other state or foreign country whose requirements for such license, as determined by the Board, are equivalent to those of the State of Minnesota. Such applicant shall submit, on forms provided by the Board, the following information:

- (1) The information required by ME 10 (b) (1) through (5).
- (2) Original or certified copy of license or certificate to practice massage issued by the state or country from which the applicant is seeking reciprocal licensure.

(f) Every person registered to practice massage in this state shall advise the Board in writing of the address of his place of residence and the address of each place at which he practices massage, and shall promptly notify the Board in writing of any change in either address."

34. ME 11 (e), by striking and deleting the whole thereof and by substituting the following in lieu and in place thereof:

"(e) An applicant whose credentials are determined by the Board to indicate ineligibility for examination shall be notified of such determination and the grounds therefor and may be granted a hearing thereon in accordance with the provisions of ME 63, by filing a statement of issues with the Board within twenty (20) days after receipt of such notice from the Board. After such hearing the Board shall notify the applicant, in writing, of its decision thereon."

35. ME 62, by striking and deleting the whole thereof and by substituting the follow-

ing in lieu and in place thereof:

"ME 62 *Accusation* A hearing to determine whether a right, license or privilege should be revoked, suspended, limited or conditioned, shall be initiated by the issuance of an accusation by the Board. The accusation shall be a written statement of charges which shall set forth in ordinary and concise language the acts or omissions with which the respondent is charged and shall be in sufficient detail to enable the respondent to prepare his defense. It shall specify the statutes and rules which the respondent is alleged to have violated. The accusation may also include any additional information which the Board deems appropriate. The accusation shall be verified by a member of the Board. The verification may be on information and belief."

36. ME 63, by striking and deleting therefrom the last four sentences thereof, and by substituting the following in lieu and in place thereof:

"If the Board is the initiating party, the statement of issues shall be served in the same manner as an accusation, and shall be accompanied by a Notice of Hearing substantially in the form set forth in ME 66. If the applicant is the initiating party, the statement of issues shall be served on the Board by registered or certified mail, addressed to the Board at its office in St. Paul, Minnesota, and such service shall be deemed a request for hearing. Within ten (10) days after such service, the Board shall deliver or mail to the applicant a Notice of Hearing, substantially in the form set forth in ME 66. In either case, the hearing shall be held not less than twenty (20) days nor more than one hundred twenty (120) days after service of the statement of issues. Hearings shall be held in St. Paul, Minnesota, at a place designated by the Board, unless the parties, by agreement, select another place within the State of Minnesota."

37. ME 64, by striking and deleting the whole thereof and by substituting the following in lieu and in place thereof:

"ME 64 *Service of Accusation; Form, Manner and Proof*

(a) Upon the issuance of an accusation, the Board shall serve a copy thereof on the re-

spondent as provided in ME 64 (b) hereof.

(b) If the respondent is a resident of the State of Minnesota and can be found therein, the accusation and all accompanying information shall be served upon respondent personally in the manner provided by law for the service of a summons in a civil action. If the respondent is not a resident of the State of Minnesota, or if the respondent is a resident of the State of Minnesota but cannot be found therein, the accusation and all accompanying information shall be served upon respondent by registered or certified mail, addressed to the most recent address theretofore furnished by the respondent to the Board, and the same shall be deemed received by respondent five (5) days after having been deposited in the United States mail, postage prepaid, addressed to such address. The appearance of respondent in the proceeding shall constitute a waiver of any defect in such service. Service may be proved by the affidavit of the person making the same."

38. ME 65, by striking and deleting the whole thereof and by substituting the following in lieu and in place thereof:

"ME 65 *Time and Place of Hearing* The Board shall determine the time and place of the hearing on the accusation which shall be held not less than twenty (20) days nor more than one hundred twenty (120) days after service of the accusation upon the respondent. The hearing shall be held in Saint Paul, Minnesota, at a place designated by the Board, unless the parties, by agreement, select another place within the State of Minnesota."

39. ME 66, by striking and deleting the whole thereof and by substituting the following in lieu and in place thereof:

"ME 66 *Notice of Hearing* A Notice of Hearing on the accusation shall be served by the Board upon respondent at the same time and in the same manner as the service of the accusation. The Notice of Hearing shall be substantially in the following form:

You are hereby notified that a hearing will be held before Minnesota State Board of Medical Examiners at
..... on
19...., at the hour of M.,

o'clock, upon the charges made in the accusation served upon you. You may be present at the hearing; may be, but need not be, represented by counsel of your own choosing; may present any relevant evidence on your own behalf and will be given full opportunity to cross-examine all witnesses who testify therein. If you fail to appear at the time and place above set forth, such failure will constitute a waiver of your right to a hearing, and Minnesota State Board of Medical Examiners may proceed upon the accusation with or without a hearing."

40. ME 71, by striking and deleting the whole thereof and by substituting the following in lieu and in place thereof:

"ME 71 *Form of Decision; Findings* Every decision and order adverse to a party to the proceeding shall be in writing and, except when such decision or order is made pursuant to stipulation with or the consent of the respondent, shall contain a statement of findings or reasons, a determination of the

issues presented, and the penalty, if any, or decision of the Board. The findings shall consist of a statement of the conclusions upon each contested issue of fact necessary to the decision. Parties to the proceedings shall be notified of the decision and order in person or by mail. A copy of the decision and order and accompanying statement of reasons together with proof of service shall be delivered or mailed, upon request, to the respondent or to his attorney of record."

BE IT FURTHER RESOLVED, that a public hearing on the adoption of the foregoing proposed changes in the Rules and Regulations of the Minnesota State Board of Medical Examiners be held on Saturday, February 17, 1968, at ten o'clock a.m. in Room 496, Lowry Medical Arts Building, St. Paul, Minnesota.

BE IT FURTHER RESOLVED, that notice of such hearing be given by the Secretary of this Board pursuant to the provisions of Minnesota Statutes, 1965, § 15.0412.

Thirty-First Annual Meeting The New Orleans Graduate Medical Assembly

The thirty-first annual meeting of The New Orleans Graduate Medical Assembly will be held March 4, 5, 6, 7, 1968, headquarters at The Roosevelt Hotel.

Nineteen outstanding guest speakers will participate and their presentations will be of interest to both specialists and general practitioners. The program will include fifty-one informative discussions on many topics of current medical interest, in addition to a clinicopathologic conference, symposia, medical motion pictures, round-table luncheons, and technical exhibits. This program is acceptable for thirty-two (32) elective hours by the American Academy of General Practice.

An interesting and enjoyable program of entertainment for visiting ladies has been planned.

Of special interest will be a one-day pre-Assembly symposium scheduled for Sunday, March 3 on "Sexual Problems in Clinical Practice." Six papers, together with a panel discussion, will be presented by six authorities on this subject.

Illness

Illness does not come from without; man creates it for himself, uses the outer world merely as the instrument with which to make himself ill, selects from that inexhaustible supply to be found in the wide world, now the spirochete of syphilis, today a piece of orange peel, tomorrow the bullet of a revolver, the day after a chill, so that he may pile on his woes. And always for the sake of getting pleasure out of it, because as a human being he finds a natural pleasure in suffering; because as a human being he has by nature a feeling of guilt, and wants to remove it by self-punishment; because he wants to escape from something or other that is uncomfortable.

—Georg Groddeck

RUSSELL H. FROST, M.D.

Dr. Russell H. Frost, 67, Edina physician and a former superintendent and medical director of Glen Lake Sanatorium, died Friday, October 27, following a prolonged illness.

The tuberculosis and pulmonary disease specialist was graduated from the University of Minnesota Medical School in 1924. He served his internship at Ancker Hospital, St. Paul.

He was a former superintendent and medical director of Buena Vista Sanatorium, Wabasha, Minnesota, the G. B. Cooley Sanatorium, Monroe, Louisiana. During World War II, Dr. Frost served in the U. S. Navy Medical Corps in the South Pacific and held the rank of Commander at the time of his discharge.

Dr. Frost was a member of the Hennepin County Medical Society, Minnesota State and American Medical associations, Minnesota and American Trudeau Medical Societies and the American College of Chest Physicians. He is a past secretary and president of the Wabasha County Medical Society, president of the Minnesota Trudeau Medical Society, and president of the Minnesota Chapter of the American College of Chest Physicians.

He was a former member of the Minnesota State Medical Association's Committee on Tuberculosis and a member of the Tuberculosis and Health Association of Hennepin County Board of Directors.

He is survived by a son and three daughters.

ERNEST M. HAMMES, M.D.

Dr. Ernest M. Hammes, 83, St. Paul neurologist and psychiatrist and former faculty member at the University of Minnesota medical school died September 30, in his home. Born in New Trier, Minnesota, he graduated from the University of Minnesota Medical School. Graduate work in neurology and psychiatry was done in Frankfurt, Germany, and Vienna, Austria.

Dr. Hammes was a past president of the Ramsey County Medical Society and a Life Member, 50-Club member and past president of the Minnesota State Medical Association. He was the recipient of the Distinguished Service Award in 1958. Also, Dr. Hammes was a member of the American Neurologic Association, a past president of the Central Neuropsychiatric Association and a charter member of the American Board of Neurology and Psychiatry. He was a former president of the Blue Shield of Minnesota and was a member of its board of directors from 1947 until his retirement.

He is survived by his wife, two daughters and a son, Dr. Ernest M. Hammes, Jr., of St. Paul.

In Memoriam

*There's nothing terrible in death;
'Tis but to cast our robes away,
And sleep at night, without a breath
To break repose 'till dawn of day.*

Montgomery

WILLIAM EMORY PROFFITT, M.D.

Dr. William E. Proffitt, 52, Minnesota Twins baseball team physician for the past seven years, died unexpectedly in his sleep, September 30. Born in Danville, Illinois, Dr. Proffitt received his medical degree from the University of Minnesota.

Dr. Proffitt had practiced medicine in Minneapolis for more than thirty years. Former Governor Orville Freeman had appointed him Chairman of the Governor's Council on Youth Physical Fitness and he was reappointed by former Governors Elmer L. Andersen and Karl F. Rolvaag, and Governor Harold LeVander.

He was a member of the Hennepin County Medical Society, American Medical Association and the Minnesota State Medical Association.

He is survived by his wife, a son and a daughter.

THEODORE H. SWEETSER, M.D.

Dr. Theodore H. Sweetser, Sr., 74, former head of the urology departments at St. Mary's and Hennepin County General hospitals, died October 8. A graduate of Central High School, the University of Minnesota and the Columbia University College of Physicians and Surgeons, Dr. Sweetser was a pioneer in correcting bladder defects in infants.

He was a past president of the Minnesota Academy of Medicine and a vice president of the State Board of Health and Vital Statistics. He taught pathology and surgery at the University of Minnesota from 1919 until his retirement in 1962.

Mayor Arthur Naftalin presented Dr. Sweetser with the distinguished service award in 1962 for his years of teaching and medical service to Minneapolis.

He was a member of the Hennepin County Medical Society, and American Medical Association, and a Life Member of the Minnesota State Medical Association.

He is survived by his wife, three daughters and two sons, one of whom is Dr. Theodore H. Sweetser, Jr., of Minneapolis.

DONALD C. VROMAN, M.D.

Dr. Donald C. Vroman, 53, anesthesiologist, died August 3 in Omaha, Nebraska. He was born in Omaha and received his medical degree from the University of Nebraska College of Medicine.

He was a member of the Hennepin County Medical Society, American Medical Association and the Minnesota State Medical Association. He also taught at the University of Nebraska College of Medicine.

He is survived by his wife and three sons.

Indications: Hypertension and many types of edema involving retention of salt and water.

Contraindications: Hypersensitivity and most cases of severe renal or hepatic disease.

Warning: With the administration of enteric-coated potassium supplements, which should be used only when adequate dietary supplementation is not practical, the possibility of small bowel lesions (obstruction, hemorrhage, and perforation) should be kept in mind. Surgery

for these lesions has frequently been required and deaths have occurred. Discontinue enteric-coated potassium supplements immediately if abdominal pain, distention, nausea, vomiting, or gastrointestinal bleeding occur.

Use with caution in pregnant patients, since the drug may cross the placental barrier and adverse reactions which may occur in the adult (thrombocytopenia, hyperbilirubinemia, altered carbohydrate metabolism, etc.) are potential

problems in the newborn.

Precautions: Antihypertensive therapy with Hygroton should always be initiated cautiously in postsympathectomy patients and in patients receiving ganglionic blocking agents or other potent antihypertensive drugs, or curare. Reduce dosage of concomitant antihypertensive agents by at least one-half. Barbiturates, narcotics or alcohol may potentiate hypotension. Because of the possibility of progression of renal damage, peri-

odic determination of the BUN is indicated. Discontinue if the BUN rises or liver dysfunction is aggravated. Hepatic coma may be precipitated.

Electrolyte imbalance, sodium and/or potassium depletion may occur. If potassium depletion should occur during therapy, Hygroton should be discontinued and potassium supplements given, provided the patient does not have marked oliguria.

Take special care in cirrhosis or

**For the
cardiac patient

a night,
consider one
Hygroton a day.**

**Hygroton®
chlorthalidone**

**new 50 mg. tablet
or 100 mg. tablet**

She was the picture of arteriosclerotic heart disease in failure. She couldn't sleep a wink without an extra pillow. Then her doctor prescribed digitalis and Hygroton.

First, her cardiac output improved. Then her breathing improved — along with her urinary output.

Nights could be a lot more pleasant for patients like this in your practice. Try it and see.

Hygroton therapy may also mean troublesome side effects for certain patients. A summary of essential prescribing information is shown below.

severe ischemic heart disease and in patients receiving corticosteroids, ACTH, or digitalis. Salt restriction is not recommended.

Adverse Reactions: Nausea, gastric irritation, vomiting, anorexia, constipation and cramping, dizziness, weakness, restlessness, hyperglycemia, hyperuricemia, headache, muscle cramps, orthostatic hypotension, aplastic anemia, leukopenia, thrombocytopenia, agranulocytosis, impotence, dysuria, transient myopia, skin rashes, urti-

caria, purpura, necrotizing angitis, acute gout, and pancreatitis when epigastric pain or unexplained G.I. symptoms develop after prolonged administration. Other reactions reported with this class of compounds include: jaundice, xanthopsia, paresthesia, and photosensitization.

Average Dosage: 50 or 100 mg. with breakfast daily or 100 mg. every other day.

Availability: White, single-scored tablets of 100 mg. and aqua tablets

of 50 mg., in bottles of 100 and 1000. (B)R46-230-D

Young, M.D. Director of Medical Services, Traverse City State Hospital, Traverse City, Michigan 49684.

Take five...

LABSTIX® provides 5 important urinary findings*—on a single reagent strip! That's *more* information than you can get from any other single reagent strip. You know the results in just 30 seconds—while the patient is still in your office—and readings are reliable and reproducible. LABSTIX is easy to handle, too. Never goes limp, even when wet, because it's made with clear, firm plastic. And results with LABSTIX are easy to read—color contrast between the test areas and the transparent plastic is clearly defined. An unexpected "positive" from testing with LABSTIX may help in detecting hidden pathology before marked symptoms are manifest.

*Blood; ketones; glucose; protein, and pH.

...Plus one

You can extend your testing scope by including ICTOTEST® Reagent Tablets, the 30-second determination for bilirubinuria—which can be an early sign of obstruction of the common bile duct, infectious hepatitis, or other liver disease. This test is also useful for detecting liver damage from carbon tetrachloride and other halogenated hydrocarbons used as industrial and household solvents. Positive findings with the urine-testing team of LABSTIX and ICTOTEST can represent significant guides to patient management in many clinical situations. "Negatives" may help rule out suspected abnormalities over a broad clinical range and are important for the patient's record.

The Nobel Conferences

Fourth annual Nobel Conference is to be held January 10-11, Gustavus Adolphus College in St. Peter. The 1968 theme is "The Uniqueness of Man."

Contact: James Wennblom at the College for information.

Mark Waters was a chain smoker. Wonder who'll get his office?

Too bad about Mark. Kept hearing the same thing everyone does about lung cancer. But, like so many people, he kept right on smoking cigarettes. Must have

thought, "been smoking all my life... what good'll it do to stop now?" Fact is, once you've stopped smoking, no matter how long you've smoked, the body begins to reverse the damage done by cigarettes, provided

cancer or emphysema have not developed. Next time you reach for a cigarette, think of Mark. Then think of your office —and your home.

The Arthritis Foundation salutes the thousands of dedicated physicians who volunteer their services in the nation's fight against crippling arthritis.

The Arthritis Foundation is the sole national voluntary health agency committed to conquering the rheumatic diseases. It provides the means for dynamic partnership between physicians and laymen to marshal leadership and resources toward the solution of this major national health problem.

The Arthritis Foundation looks forward to rapid growth with increasing opportunity for physicians to participate in the arthritis movement. For further information about The Arthritis Foundation and its programs write to the Foundation chapter in your community or to the Medical Department, Box 2525, New York, N.Y. 10001.

Physician's Diary

Two faculty members of the University of Minnesota Medical School, **Doctors James F. Koerner and James H. Moller**, were named 1967 winners of the Minnesota Medical Foundation Distinguished Faculty Teaching Awards.

* * *

Dr. and Mrs. J. E. Schroepel were given a plaque as the annual Citizen's Award for thirty years of service to Winthrop.

* * *

A St. Paul, Minnesota Physician, **A. Frank Adair, M.D.**, will return in mid-October from work in Project HOPE's medical teaching-treatment mission to Cartagena, Colombia. He worked as a volunteer aboard the floating medical center S. S. HOPE.

* * *

Dr. Edward H. Soule, a member of the Section of Surgical Pathology of the Mayo Clinic, was awarded the gold medal, given for the best educational exhibit, of the American Society of Clinical Pathologists at the annual meeting of that society in Chicago in December. The title of the exhibit was "Primary Tumors of the Soft Tissues of the Extremities."

* * *

The following physicians were inducted as new Fellows of the American College of Surgeons in October: **Doctor Lynn C. Stoker** of Albert Lea; **Doctors Eugene F. Bernstein, Aldo R. Castaneda, Harrison H. Farley, John H. Glaeser, Hermann W. Heupel, Richard E. Larson, Arnold S. Leonard, Richard R. Lund, Donald G. McQuarrie, Demetre M. Nicoloff, Hyman M. Paisner, David E. Raab and Melvin E. Sigel** of Minneapolis; **Doctor John N. Simons** of Rochester; **Doctors Bernard Gooft, Max E. Harris and George T. Tani** of St. Paul and **Frederick C. Wuest** of Wayzata.

* * *

New Locations: **Dr. Cyril J. Dillenburg** has joined the staff of St. Francis and Bethesda Hospitals in Crookston. . . . **Dr. E. P. Bryant** has left the Ellendale Clinic to enter into a group practice in Silver Bay. . . . **Dr. Roger J. Benjamin** has opened up a private medical practice in Owatonna. . . . **Doctors**

Gregory and Wanda Kaminski have joined **Dr. S. F. Ceplecha** in Redwood Falls.

* * *

Dr. Frederick Van Bergen, head of the University of Minnesota's Department of Anesthesiology, was named president of the Academy of Anesthesiology at the Academy's 36th annual meeting in Scottsdale, Arizona, in September.

* * *

Walter F. Larrabee, Jr., M.D., is the acting medical director at the Willmar State Hospital. He succeeded **Dr. Donald C. Carter** who resigned to assume a full-time faculty position at the University of Missouri school of medicine.

* * *

Dr. L. K. Onsgard was honored by the residents of Houston upon occasion of his leaving Houston after thirty-seven years of service. Dr. and Mrs. Onsgard will reside in St. Petersburg, Florida.

* * *

Dr. Malcolm Dockerty, a Mayo Clinic pathologist, has received an honorary doctor of laws degree from his alma mater, Prince of Wales College, Prince Edward Island, Canada.

* * *

A Grand Marais physician received the American Cancer Society National Divisional Award at a recent membership dinner meeting.

A bronze medal and a citation for "outstanding contribution to the control of cancer" was awarded **Dr. R. A. MacDonald**.

The presentation was made by **Dr. Donald E. Stewart**, Crookston surgeon, president of the Society's Minnesota Division.

* * *

Dr. Lynn C. Stoker, Albert Lea surgeon, has been inducted into the Fellows of the American College of Surgeons.

* * *

Dr. T. R. Fritsche received the Harold S. Diehl outstanding physician award last October from the University of Minnesota Medical Alumni Association.

* * *

Dr. D. J. Dummer, New Brighton Clinic, has been re-elected to active membership in the American Academy of General Practice.

Venereal Disease A Serious National Problem, Says AMA

Venereal disease is spreading so rapidly that it now represents this nation's most urgent communicable disease problem.

VD is hitting particularly hard among teenagers and young adults, according to the American Medical Association.

The venereal diseases are infecting about two Americans a minute—3,000 a day, or 1,100,000 a year. Cases of infectious syphilis have almost tripled in this country in the past five years. More than a million

new cases of gonorrhea are developing annually.

VD can blind, cripple, and even kill.

The ravages of venereal diseases are all needless tragedy, says the AMA, because both syphilis and gonorrhea can be avoided. If contracted, they can be cured by prompt medical treatment.

The cure for both diseases—penicillin—has been available since 1943. Any family physician or public health clinic can administer

prompt treatment.

Venereal disease is caused by intimate personal contact.

Complacency, ignorance, and a free-and-easy attitude toward moral standards are partly responsible for the spread of VD; the increasing use of alcohol, especially among young people, also plays a role.

Authorities believe, however, that thousands of young people simply aren't aware of the dangers of VD. Once infected, they are complacent about treatment.

One of the first signs of syphilis may be a painless, ulcerating sore. Gonorrhea produces inflammation of the genital and urinary tracts, and a discharge of pus.

A person may contract syphilis and be unaware that he has the disease. After the first symptoms, the germs may remain hidden in the body for as long as 20 years before any damage is discovered. Then the person may become crippled, develop heart disease, blood vessel disease, blindness, or show mental symptoms. Even death may result from this hidden stage of syphilis.

If left untreated, gonorrhea may be responsible for arthritis, endocarditis, sterility, and blindness.

If a person suspects he may have contracted venereal disease, he should go to a physician immediately.

VD should be treated promptly by a physician.

Minnesota Medicine at a Glance

Diverticulitis of Pelvic Colon—Loffer and Bergquist

Page 1793

That diverticulitis of the pelvic colon can simulate gynecological disorders is well known but needs emphasis. The authors present a case in which a primary adenocarcinoma of the endometrium was complicated by a pelvic mass due to a ruptured colonic diverticulum. The true nature of things could only be suspected preoperatively but, once recognized at laparotomy, presented no special therapeutic problem.

Communication between Parents and Child—Burke

Page 1801

Communication, the sharing of feelings, ideas and ideals between parents and children, is the means by which children grow to adults and adults become mature. This quick view of the changing interactions between parents and children will be a good review for pediatricians, family physicians and for all physicians rearing children of their own.

Cardiac Resuscitation in a Community Hospital

Page 1925

Ho and Quattlebaum.

The experiences of a medium-sized community hospital in the field of cardiac resuscitation and defibrillation are presented.

A total of 119 patients were diagnosed as having had ventricular fibrillation or cardiac standstill over a period of three years. Satisfactory cardiac action was restored in 40 per cent. Twenty patients survived to be discharged, all of them well when they left the hospital.

The preparation, organization and procedure for diagnosis and treatment of cardiac arrest are reviewed.

Out of these Emotions

I am often asked, "How did you happen to study medicine?" Then I think of that strange "yellow day" in September of 1881, when the whole of the Eastern States were masked in an uncanny, sulphur-colored light—a mysterious, sinister light for which science has given no explanation.

It was on that day that I followed a rude country wagon moving slowly out from the Adirondack woods, over the long rough road homeward—its burden my brother's body. Somehow there was a weird, almost vaguely sympathetic fitness in the strange yellow light, toning with my grief and my despair.

I felt completely adrift, my whole plan of life in sudden and overwhelming chaos. The thought kept recurring; if I had known more of illness and the means of combating it, I might have been able to do more for him. Out of these emotions came the decision which set the course of my life.

I would become a doctor.*

Editor's Note: Alfreda Withington, after graduating from the Woman's Medical College of the New York Infirmary, spent her life in medical practice, living to the venerable age of ninety-one.

VOLUME 50 INDEX

JANUARY-DECEMBER, 1967

OFFICE OF PUBLICATION

375 Jackson - - - - - Saint Paul, Minnesota, 55101

A

- A Mass in the Neck—The Diagnostic Approach. George F. Reed 941
- A New Intra-Articular Steroid with Prolonged Anti-Inflammatory Action. Paul J. Bilka 483
- Abortion, An Obstetrician's View of Therapeutic. Erick Y. Hakanson 23
- Abortion, Criminal—Deaths and Suicides in Pregnancy in Minnesota 1950-1964. Alex Barno 11
- Abortion Laws—Inequitable, Inconsistent and Hence Inexcusable. Fred A. Lyon 17
- Abortion, Therapeutic, Medical Indications for—An Obstetrician's View. David G. Decker 29
- Acoustic Tumors—Diagnosis and Management. William F. House and William E. Hitselberger 873
- Addiction—Cases Treated on a Psychiatric Service. Carl D. Koutsky and Theodore G. Larson 189
- Advanced Laryngeal and Laryngopharyngeal Cancer—Combined X-ray Therapy and Surgery. Joseph L. Goldman 995
- Advantages and Limitations of a Hearing Aid. Raymond Carhart 823
- Allergic Dysfunction—The Fundamentals. Harry P. Schenck 1029
- Allergy, The Importance of Corn. Kenneth J. Johnson 33
- Amebic Liver Abscess. Harrison H. Farley and John H. Linner 477
- Amniocentesis—Effect of Contamination of Amniotic Fluid with Either Maternal Blood or Meconium. William N. Spellacy, W. D. Cohen, R. A. Diamond 1055
- An Obstetrician's View of Therapeutic Abortion. Erick Y. Hakanson 23
- Anatomy of the Lymphatics—Relationship to the Dissemination of Malignancies and Infections. Joel J. Pressman and Mildred V. Burtz 989
- Angiosarcoma of Lungs and Adrenal Gland—Unusual Clinical and Pathologic Manifestations. William H. Kern, Reginald H. Smart and Russell P. Sherwin 1339
- Annessa, Guilo, Read, Raymond C. and Katz, William: Gastric Duplication with Pancreatic Communication Presenting as Pancreatitis 1175
- Aortic Stenosis and Unexplained Gastrointestinal Bleeding. Leonard Nordstrom and James Myhre 1623
- Arteriovenous Fistula—An Unusual Cause of Heart Failure in An Old Man. David A. Berman, Yoshio Sako, Jafer Kuaity 345
- Assessment of Vertigo. W. J. McNally 1003
- Aural Symptoms of Psychosomatic Origin. Gordon D. Hoople 1025

ABSTRACTS, BRIEFS AND COMMENTARIES

January	113
February	257
March	421
April	591
May	781
July	1137
August	1257
September	1423
November	1743
December	1903

ADVANCES

- Bacteremia Due to Gram-Negative Bacilli—Some Current Concepts of Therapy.
Part I—William J. Martin 397
Part II—559
- Cloxacillin for Prophylaxis in Oral Surgery. Daniel E. Waite, Alexander Schirger, William J. Martin 1247
- Creevy, C. D.: Vesicoureteral Reflux in Children—A Brief Review 757
- Lacerations of the Hand Tendons—Current Concepts of Treatment. Hamlet A. Peterson and Paul R. Lipscomb 101
- Lipscomb, Paul R. and Peterson, Hamlet A.: Lacerations of the Hand Tendons—Current Concepts of Treatment 101
- Marcoux, André and Martin, William J.: Untoward Reactions Associated with Antimicrobial Therapy.
Part I—Cardiovascular, Respiratory and Gastrointestinal Reactions 1393
Part II—Hematopoietic and Genitourinary Reactions 1571
Part III—Metabolic and Electrolytic, Skeletal, Neuromuscular and Dermal Reactions with Comments and Conclusions 1713
- Martin, William J.: Bacteremia Due to Gram-Negative Bacilli. Some Current Concepts of Therapy.
Part I—397
Part II—559
- Martin, William J. and Marcoux, André: Untoward Reactions Associated with Antimicrobial Therapy.
Part I—Cardiovascular, Respiratory and Gastrointestinal Reactions 1393
Part II—Hematopoietic and Genitourinary Reactions 1571
Part III—Metabolic and Electrolytic, Skeletal, Neuromuscular and Dermal Reactions with Comments and Conclusions 1713
- Martin, William J.: Semisynthetic Penicillins 1893
- Martin, William J., Waite, Daniel E. and Schirger, Alexander: Cloxacillin for Prophylaxis in Oral Surgery 1247
- Peterson, Hamlet A. and Lipscomb, Paul R.: Lacerations of the Hand Tendons—Current Concepts of Treatment 101
- Schirger, Alexander, Martin, William J. and Waite, Daniel E.: Cloxacillin for Prophylaxis in Oral Surgery 1247
- Semisynthetic Penicillins. William J. Martin 1893
- Untoward Reactions Associated with Antimicrobial Therapy. André Marcoux and William J. Martin
Part I—Cardiovascular, Respiratory and Gastrointestinal Reactions 1393
Part II—Hematopoietic and Genitourinary Reactions 1571
Part III—Metabolic and Electrolytic, Skeletal, Neuromuscular and Dermal Reactions with Comments and Conclusions 1713
- Vesicoureteral Reflux in Children—A Brief Review. C. D. Creevy 757
- Waite, Daniel E., Schirger, Alexander and Martin, William J.: Cloxacillin for Prophylaxis in Oral Surgery 1247

ATHLETIC INJURIES

- Erickson, Donald J. and Henderson, Edward D.: Preseason Conditioning Exercises for High School Football Players 1263

BOOK REVIEWS

Alcoholism, Its Facets and Phases. Marvin A. Block 1141

Applied Hypnosis and Positive Suggestion. G. A. Ulett and D. B. Peterson 239

Appraisal of Current Concepts in Anesthesiology. Edited by John Adriani 783

Atlas of Cryosurgical Techniques in Ophthalmology. Charles D. Kelman 1141

Atlas of General Surgery. Joseph R. Wilder 1583

Birth Control and Conscience. M. H. Mothersill 1911

Blood Diseases of Infancy and Childhood. Carl H. Smith 1141

Current Practice in Orthopaedic Surgery. Adams 415

Dermatopathology. Hamilton Montgomery 1745

Diabetes for Diabetics. George F. Schmitt 1421

Die Arthrosis Deformans Des Kniegelenkes. Walter Mohring 595

Early Management of Acute Trauma. Nahum 239

Epidemiological Study of Cancer and Other Chronic Disease. National Cancer Institute 117

International Symposium on Genes and Chromosomes. Juan I. Valencia and Rhoda F. Grell 117

International Symposium on the Nucleolus: Its Structure and Function. National Cancer Monograph 1421

Medical Pharmacology, Principles and Concepts. Andreas Goth 415

Mental Retardation. Elizabeth W. Reed and Sheldon C. Reed 1261

Modern Treatment—Treatment of Gastrointestinal Infections: Treatment of Superinfections. Marcel Patterson and Harold J. Simon 595

Modern Treatment. Treatment of Neuromuscular Disorders. Frank M. Howard, Jr. 1583

Pathology. W. A. D. Anderson, editor 595

Pediatrician's Ophthalmology. Edited by Sumner D. Liebman and Sydney S. Gillis 1261

Primer of Peripheral Vascular Disease. Travis Winsor and Chester Hyman 783

Progress in Clinical Cancer. Irving M. Ariel 415

Questions and Answers in Orthopaedics. Goodman and Schoedinger 783

Surgery of Rheumatoid Arthritis. Leonard Marmor 1911

Surgical Diseases of the Chest. Edited by Brian Blades 1261

Synopsis of Neurology. Francis M. Forster 117

Textbook for Medical Assistants. Lawton-Foy 1911

The Thymus: Experimental and Clinical Studies. G. E. W. Wolstenholme and Ruth Porter, editors 1745

Treatment of Superinfections. Edited by Marcel Patterson and Harold J. Simon 595

C

California Encephalitis—Five Cases in Southeastern Minnesota. C. M. Johnson and C. W. Rogers 1203

Caplan's Syndrome. David E. Dines and L. Emmerson Ward 1787

Carcinoma of the Pancreas and the Ampulla of Vater—Treatment of. Yoshio Sako 169

Cardiac and Pulmonary Dyspnea—Clinical Differentiation. David E. Dines and Thomas W. Parkin 1181

Carlhart, Raymond: The Advantages and Limitations of a Hearing Aid 823

Cartilaginous Tumors of the Larynx—Chondrosarcoma of the Larynx. Robert M. Gasior and William H. ReMine 1197

in chronic illness

B and C vitamins are part of therapy: An imbalance of water-soluble vitamins and chronic illness often go hand in hand. STRESSCAPS capsules, containing therapeutic quantities of vitamins B and C, are formulated to meet the increased metabolic demands of patients with physiologic stress. In chronic illness, as with many stress conditions, STRESSCAPS vitamins are therapy.

 Stresscaps[®] Stress Formula Vitamins <u>Lederle</u>	 FOR PROFESSIONAL RECOMMENDATION ONLY	Each capsule contains: <table> <tr><td>Vitamin B₁ (as Thiamine Mononitrate)</td><td>10 mg</td></tr> <tr><td>Vitamin B₂ (Riboflavin)</td><td>10 mg</td></tr> <tr><td>Vitamin B₆ (Pyridoxine HCl)</td><td>2 mg</td></tr> <tr><td>Vitamin B₁₂ Crystalline</td><td>4 mcgm</td></tr> <tr><td>Vitamin C (Ascorbic Acid)</td><td>300 mg</td></tr> <tr><td>Niacinamide</td><td>100 mg</td></tr> <tr><td>Calcium Pantothenate</td><td>20 mg</td></tr> </table> Recommended intake: Adults, 1 capsule daily, for the treatment of vitamin deficiencies. Supplied in decorative "reminder" jars of 30 and 100; bottles of 500.	Vitamin B ₁ (as Thiamine Mononitrate)	10 mg	Vitamin B ₂ (Riboflavin)	10 mg	Vitamin B ₆ (Pyridoxine HCl)	2 mg	Vitamin B ₁₂ Crystalline	4 mcgm	Vitamin C (Ascorbic Acid)	300 mg	Niacinamide	100 mg	Calcium Pantothenate	20 mg

WH IS A SIGNIFICANT COMPONENT OF THE CLINICAL PROFILE

LIBRIUM[®]
(chlordiazepoxide HCl)

Also available as
LIBRITABS[™] (chlordiazepoxide)
5-mg, 10-mg, 25-mg tablets

Before prescribing, please consult complete product information, a summary of which follows:

Contraindications: Patients with known hypersensitivity to the drug.

Warnings: Caution patients about possible combined effects with alcohol and other CNS depressants. As with all CNS-acting drugs, caution patients against hazardous occupations requiring complete mental alertness (e.g., operating machinery, driving). Though physical and psychological dependence have rarely been reported on recommended doses, use caution in administering to addiction-prone individuals or those who might increase dosage; withdrawal symptoms (including convulsions), following discontinuation of the drug and similar to those seen with barbiturates, have been reported. Use of any drug in pregnancy, lactation, or in women of child-bearing age requires that its potential benefits be weighed against its possible hazards.

Precautions: In the elderly and debilitated, and in children over six, limit to smallest effective dosage (initially 10 mg or less per day) to preclude ataxia or oversedation, increasing gradually as needed and tolerated. Not recommended in children under six. Though generally not recommended, if combination therapy with other psychotropics seems indicated, carefully consider individual pharmacologic effects, particularly in use of potentiating drugs such as MAO inhibitors and phenothiazines. Observe usual precautions in presence of impaired renal or hepatic function. Paradoxical reactions (e.g., excitement, stimulation and acute rage) have been reported in psychiatric patients and hyperactive aggressive children. Employ usual precautions in treatment of anxiety states with evidence of impending depression; suicidal tendencies may be present and protective measures necessary. Variable effects on blood coagulation have been reported very rarely in patients receiving the drug and oral anticoagulants; causal relationship has not been established clinically.

Adverse Reactions: Drowsiness, ataxia and confusion may occur, especially in the elderly and debilitated. These are reversible in most instances by proper dosage adjustment, but are also occasionally observed at the lower dosage ranges. In a few instances syncope has been reported. Also encountered are isolated instances of skin eruptions, edema, minor menstrual irregularities, nausea and constipation, extrapyramidal symptoms, increased and decreased libido—all infrequent and generally controlled with dosage reduction; changes in EEG patterns (low-voltage fast activity) may appear during and after treatment; blood dyscrasias (including agranulocytosis), jaundice and hepatic dysfunction have been reported occasionally, making periodic blood counts and liver-function tests advisable during protracted therapy.

Usual Daily Dosage: Individualize for maximum beneficial effects. *Oral*—Adults: Mild and moderate anxiety and tension, 5 or 10 mg t.i.d. or q.i.d.; severe states, 20 or 25 mg t.i.d. or q.i.d. Geriatric patients: 5 mg b.i.d. to q.i.d. (See Precautions.)

Supplied: Librium[®] (chlordiazepoxide HCl) Capsules, 5 mg, 10 mg and 25 mg—bottles of 50. Libritabs[™] (chlordiazepoxide) Tablets, 5 mg, 10 mg and 25 mg—bottles of 100. With respect to clinical activity, capsules and tablets are indistinguishable.

Tears without grief

Crying Spells—psychic tension with depressive symptoms?

"I don't know what's the matter with me lately...I cry and I cry... and I really don't know why I do."

A woman often is not conscious of the real reasons for her crying spells or refuses to admit them to herself. On probing, you may find that frequent weeping, like insomnia or neurotic fatigue, often is an expression of psychic tension. She needs sympathy and reassurance, and perhaps a calming agent to help her over her crisis. Consider prescribing Valium (diazepam) for her. It usually reestablishes calmness promptly. Crying spells and other secondary depressive symptoms normally subside as the tension is relieved. Your patient then can cope more easily with stresses to which she is subjected. Valium (diazepam) is generally well tolerated, and on proper maintenance dosage usually does not impair mental acuity or ability to function. If side effects such as ataxia and drowsiness occur, they usually disappear with dosage adjustment.

Before prescribing, please consult complete product information, a summary of which follows:

Contraindications: Infants, patients with history of convulsive disorders, glaucoma or known hypersensitivity to drug.

Warning: Not of value in the treatment of psychotic patients, and should not be employed in lieu of appropriate treatment.

Precautions: Limit dosage to smallest effective amount in elderly or debilitated patients (not more than 1 mg, one or two times daily initially) to preclude ataxia or oversedation, increasing gradually as

needed or tolerated. As is true of all CNS-acting drugs, until correct maintenance dosage is established, advise patients against possibly hazardous procedures requiring complete mental alertness or physical coordination. Driving during therapy not recommended. In general, concurrent use with other psychotropic agents is not recommended. If such combination therapy is used, carefully consider individual pharmacologic effects—particularly with known compounds which may potentiate action of Valium (diazepam), such as phenothiazines, barbiturates, MAO inhibitors and other antidepressants. Advise patients against simultaneous ingestion of alcohol or other CNS depressants. Safe use in pregnancy not established. Employ usual precautions in treatment of anxiety states with evidence of impending depression; suicidal tendencies may be present and protective measures necessary. Observe usual precautions in impaired renal or hepatic function.

Periodic blood counts and liver function tests advisable in long-term use. Cease therapy gradually.

Side Effects: Side effects (usually dose-related) are fatigue, drowsiness and ataxia. Also reported: mild nausea, dizziness, blurred vision, diplopia, headache, incontinence, slurred speech, tremor and skin rash; paradoxical reactions (excitement, depression, stimulation, sleep disturbances, acute hyperexcited states, hallucinations); changes in EEG patterns during and after drug treatment. Abrupt cessation after prolonged overdosage may produce withdrawal symptoms (convulsions, tremor, abdominal and muscle cramps, vomiting, sweating) similar to those seen with barbiturates, meprobamate and chlordiazepoxide HCl.

Dosage: *Adults:* Mild to moderate psychoneurotic reactions, 2 to 5 mg b.i.d. or t.i.d.; severe psychoneurotic reactions, 5 to 10 mg t.i.d. or q.i.d.; alcoholism, 10 mg t.i.d. or q.i.d. in first 24 hours, then 5 mg t.i.d. or q.i.d. as needed; muscle spasm with cerebral palsy or athetosis, 2 to 10 mg t.i.d. or q.i.d. *Geriatric patients:* 1 or 2 mg/day initially, increase gradually as needed and tolerated. (See Precautions.)

Supplied: Valium® (diazepam) Tablets, 2 mg, 5 mg and 10 mg; bottles of 50 and 500.
